NEW YORK, SATURDAY, JANUARY 4, 1913

Published by Munn & Co. Incorporated. Charles Allen Munn, President. Frederick Converse Beach, Secretary and Treasurer all at 361 Broadway, New York

Entered at the Post Office of New York, N. Y., as Second Class Matter. Trade Mark Registered in the United States Patent Office.

Subscription Rates

Subscription one year	$3.00
Postage prepaid in United States and possessions, Mexico, Cuba and Panama	
Subscriptions for Foreign Countries, one year, postage prepaid	4.50
Subscriptions for Canada, one year, postage prepaid	3.75

The Scientific American Publications

Scientific American (established 1845)	per year	$3.00
Scientific American Supplement (established 1876)	"	5.00
American Homes and Gardens	"	3.00

The combined subscription rates and rates to foreign countries including Canada, will be furnished upon application. Remit by postal or express money order, bank draft or check.

Munn & Co., Inc., 361 Broadway, New York

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles *short* and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement.

Retrospect of the Year 1912

Civil Engineering

In a review of civil engineering works of the past year the progress of the Isthmian Canal at Panama naturally receives the first attention, and it is sufficient to say that during the year this stupendous task has moved toward its approaching conclusion with that uninterrupted regularity which has marked the work as carried on under Col. Goethals. Not even the enormous slides in the Culebra cut, the bulging of the slopes at Gatun Dam due to the hydraulic action of the semi-liquid core of the dam, or the threatened settlement of the guide walls at the locks have dismayed the working force for a moment. Each crisis has been met and mastered, and to-day everything promises fair for the sending of the first ship through the canal (in an experimental way) in the autumn of the present year and the official opening on January 1st, 1915, not only of a completed canal, but of a canal whose mechanical and human operating forces are in thorough working order. Next to the Panama Canal in the magnitude of the total excavation is the Ambrose Channel, 40 feet deep and 2,000 feet wide, extending for nearly seven miles from deep water into New York Harbor. Not many people understand that this great work, which has been done so unostentatiously, has involved the excavation of nearly seventy million cubic yards of material, or just one third of the amount that will have been taken out when the Panama Canal is completed. The canal is 98 per cent dug and the early months of the present year will see the task completed. The Ambrose Channel will form another monument to the efficiency of that able professional body, the Engineer Corps of the United States Army. The year has seen steady work done upon yet another great engineering task, that of damming the Mississippi River at Keokuk, Iowa, where a dam about a mile in length is being constructed, and a hydraulic electric plant with a first installation of some 200,000 horse-power will serve to transform the energy of the impounded water into light and power. The power house will be extended from time to time as the commercial demand increases. Great progress has been made on the New York State Barge Canal, which will make it possible for thousand-ton barges to navigate between the Great Lakes and New York city. Practically the whole of this great work of reconstruction is under way, much of it is completed, and the opening of the canal is promised by the year 1915. Another important waterway, the Welland Canal, a Canadian competitor of the State Barge Canal, is to be greatly enlarged at an estimated cost of $45,000,000. The improvement will extend from Port Colborne to a short distance north of Thorold. The depth will be increased from 14 to 25 feet and 30 feet in the locks, and it will be widened from 150 to 200 feet. The locks will be reduced from 22 to 7, and eight hours' time will be saved between Port Colborne and Port Dalhousie. Such good work has been done on the Cape Cod Canal that its completion and opening are promised during the next winter or, at the latest, in the early spring of 1914. This waterway will provide a 25-foot depth from Barnstable Bay to the 30-foot depth in Buzzard's Bay, a distance of 12¼ miles. The work of providing an additional daily water supply of 500,000,000 gallons for New York, known as the Catskill Water Supply, has made great advancement during the past year. The Ashokan Dam is practically completed, the huge siphon, passing 1,100 feet below the Hudson River, is concreted, much of the aqueduct, which is from 12 to 17 feet in diameter, is also completed, the shafts for the deep-water tunnel below New York are driven and in some cases the headings of the tunnel have been broken through, and it is promised that this year water from the Catskills will be turned into the Croton Reservoir, thereby removing any immediate danger of a water famine in this city. Mention should be made of the work that has been done in completing the Los Angeles Aqueduct, through which water will be supplied to that city from a point in the Sierra Mountains, 240 miles distant. The work will include forty-seven miles of tunnel and nine and one third miles of inverted steel siphons, some of which are ten feet in diameter.

Electrical Engineering

Although no single achievement stands out very prominently in the field of electrical engineering for the year 1912, nevertheless there has been general activity and a steady, healthy growth in all lines of electrical work. This has been marked by a determined effort to promote the electric vehicle for pleasure and for commercial service and to promote the introduction of electricity on the farm. One enterprising New England company has introduced the very novel idea of having a traveling electrical exhibition. The show is given in a circus tent which is set up in various agricultural communities in the neighborhood of the central station plant, and farmers and suburbanites are given an opportunity of seeing for themselves the advantages of electrical apparatus on their farms and in their own homes. One of the most important electrical undertakings has already been mentioned in the previous paragraph, because in its construction it is of particular interest to the civil engineer. We refer to the Keokuk Dam across the Mississippi River, which will provide hydro-electric power of something like 1,000,000 horse-power. In California, the power of the water flowing through the Los Angeles Aqueduct is to be fully utilized. Seven hydro-electric plants are being constructed and it is estimated that they will generate 118,000 horse-power. According to the report of the Commissioner of Corporations, 6,000,000 horse-power is now developed in this country by water and several million more could possibly be developed from the same source. Abroad there have been some very important water power developments, particularly in Norway. There preparations are under way to develop 500,000 horse-power in addition to the existing 430,000 horse-power. This doubling of the amount of current generated is due to the demand of electro-technical industries. There has been some activity in the electrification of steam railroads. Locally, the most important item for the year is the work of the New Haven Railroad in extending its electrified zone from Stamford to New Haven. The new equipment will be practically identical with that on the existing electric road, indicating that the company is evidently satisfied with the efficiency of its present electrical installation. The most interesting railroad work abroad has been the completion of a Jungfrau railroad, which provides access to the summit of that lofty peak. In Mexico an electric railroad has been proposed to run to the summit of Mt. Popocatepetl, not for the purpose of carrying passengers, but to permit of transporting sulphur from the mine in the crater. Ten enormous electric locomotives are being built for the Swiss railways. They will weigh 108 tons each and will be the most powerful single unit electric locomotives so far, being capable of developing 2,500 horse-power at a speed of fifty miles per hour. Each can exert a draw bar pull of 40,000 pounds. The use of the storage battery for traction purposes is increasing. Recently a storage battery train was built and shipped to Cuba for use on the Havana Railroad. Storage battery cars are meeting with continued favor in New York city, and the storage battery locomotive is being used very extensively in the aqueduct tunnels and the new subway work. The most prominent event in the field of wireless telegraphy has been the completion of the Naval Station at Arlington with its 600 foot antennae. In Germany, at Nauen, a tower 970 feet high is being erected, which is expected to have a radius of 6,000 miles. In France a system of wireless telegraphy without sparks has been developed, giving wave-lengths about ten times greater than has heretofore been possible with a given antenna of the sheet type. Following the loss of the "Titanic" in April, radical measures were taken to provide for constant attendance upon the wireless telegraph apparatus on board ship. In addition to this, there have been important regulations to control the amateur wireless telegraph operator. No amateur is now allowed to operate a transmitting instrument of power sufficient to reach beyond the borders of his State, without obtaining a license from the Government. Transatlantic wireless telegraphy is now conducted on a reliable commercial basis. Before dropping the subject of wireless telegraphy we must refer to experiments with the wireless control of torpedoes in which some material progress has been made during the year. Some progress has been made in long distance telephony. England is now able to talk directly with Switzerland. This long distance communication is of course made possible by the use of Pupin coils in the lines. In this country the telephone is being increasingly used for train dispatching. Experiments with the telegraphic transmission of photographs are still being carried on abroad, although little if anything has been done in this country as yet. The electric steel furnace is steadily making its way into the steel plant. We have recently learned that an all-electric steel melting plant is being built in Sheffield, England, the home of the steel industry. At the Panama Canal electricity is to be used very extensively for light and power purposes. The towing engine at the locks will be driven by electricity, and the lock gates will also be operated by electric motors. To furnish the power necessary for this purpose, a hydro-electric plant is being built which will obtain its power from Gatun Lake. Altogether there will be about 7,000 lamps at the locks and 1,000 individual motors.

Naval and Military.

Conditions in the Navy during the past year have been eminently satisfactory, with the one important exception that Congress saw fit to cut down the annual appropriation for battleships just one half, authorizing the construction of only one such vessel this year. A striking evidence of the efficiency and preparedness of the Navy was afforded by the great review at New York last autumn, when, at short notice, a fleet of 123 ships, aggregating 720,480 tons was gathered in the North River. In 1912 there were 168 ships in active service or ready for service as against twenty on the repair list—certainly an excellent showing. The quality of our ships is excellent, but in number they are too few. When all ships built, building or authorized are taken into account, we find ourselves dropping quickly behind the other leading powers, for in dreadnoughts, it is shown that England has 80 ships, Germany, 23, and the United States, 13 only. On the same basis, the relative order of tonnage is Great Britain, 2,478,152 tons, Germany 1,124,267 tons, and the United States, 808,485 tons. Congress should authorize at least three dreadnoughts this year to repair last year's deficiency. Oil fuel has proved such a success that it will probably be used exclusively in future warships. The oil burning destroyers are able to run at all speeds with perfectly clean smokestacks, and the new battleships, "Nevada" and "Oklahoma," of 27,500 tons displacement, will be fired exclusively with oil. Apart from the important feature of invisibility, due to the absence of smoke, there are other advantages of the reduction in the number of smokestacks, the abolition of bunkers, the oil being carried in the double bottom, and a great reduction in the operating staff. The mechanical reduction gear on the "Neptune" has proved to be satisfactory—eminently so, and new turbines, more suitable to the conditions, are being built, which are expected, in connection with the gear, to show the many advantages of economy and convenience of operation which have been predicted, both in the motive power and the control of the ship. The "Jupiter," which is to have electric reduction gear, will probably undergo her trials in the near future, and it is confidently believed that the theoretical advantages of this type will be fully demonstrated. During the year foreign powers have continued to build battleship-cruisers which combine a battery of the heaviest guns with fair armored protection and extraordinary speed. The "Moltke" and "Goeben" of the German navy are credited with trial speeds of 29 to 30 knots, and the British "Lion," carrying eight 13.5 guns, has made an average of 33 knots in six trials on the measured mile. We should build at least one experimental ship of this type. The destroyer continues to prove its efficiency and general serviceableness, and the leading powers are agreed that at least four of these ships should be built to each battleship. The submarine increases in size, speed and offensive power. It is proving so successful that some authorities consider that it may dominate the warfare of the future. The coast fortifications of the United States are practically completed, and work has been pushed actively on the fortifications of the Philippines and the Panama Canal. The new army 14-inch gun gave every satisfaction in its earlier trials at the proving grounds. One wirewound and two hooped guns of this type have passed successfully through their trials. The fourth gun, when fired with its maximum charge, exploded, the breech and outer hoop being torn apart. This matter is now under investigation, and our ordnance officers believe that the defect is one that can be fully remedied in future guns. The disappearing mount is favored for coast fortifications, but some turret mountings are being built for the defenses at Manila.

The Merchant Marine.

In any review of the past year in matters affecting the Merchant Marine, the tragic loss of the "Titanic" naturally receives first consideration. Next to the pitiful loss of some 1,500 people, the most disquieting feature

of the tragedy was the fact that the ship was the latest and largest of the great ocean liners, and that she came from one of the finest shipbuilding yards in the world. It is now well understood that her loss was due to the fact that she was insufficiently sub-divided. The test was of course a supreme one, nevertheless she should have been so well protected as to stay afloat, even under that terrible ordeal. The disaster drew attention to the fact that shipbuilders have not lived up to the high standards of under-water protection set by Brunel, when he built the "Great Eastern" over half a century ago. That the White Star Company, at least, learned this lesson, is shown by the fact that her sister ship, the "Olympic," is now at the Belfast yards, where she is being provided with a double skin throughout the greater part of her length, and her subdivision is being greatly amplified. Similar changes are being made in the "Britannic," which is now under construction. Both the Senate inquiry in this country and that under Lord Mersey in Great Britain emphasized the necessity, not merely of providing life-boats for everyone on board, but of so thoroughly subdividing a ship that a repetition of the "Titanic" disaster will be rendered impossible.

Great as are the ocean steamships of the present day, their dimensions still continue to increase. Next spring, the "Imperator," 919 feet in length, will be dispatched by the Hamburg American Line to this port, and about the same time the Cunard Company will send over on her maiden voyage a ship of approximately the same size, something over 900 feet in length, which will be an enlarged "Mauretania" with somewhat less speed. The past year has seen an active revival of the burning question of providing longer piers to accommodate these ships at the port of New York, and a bill has been introduced into the House favoring the straightening of the pierhead lines from the Battery to Pier 80, which will provide accommodations for twenty piers from 950 to 1,040 feet in length. The oil engine continues its invasion of the field of marine transportation, which for so long has been held exclusively by the steam engine. The successes of the past year have been truly phenomenal. Two large freight steamers, the "Selandia" and the "Christian X" have proved successful even beyond expectations. These are sister ships. The "Christian X" made her maiden voyage across the Atlantic last September. She is 370 feet long, has a displacement of 10,300 tons, and is driven by twin Diesel engines of a combined maximum indicated horse-power of 2,500. She steamed, on her maiden voyage from Hamburg to Havana, 4,027 miles at a speed of 11 1 knots, with a consumption of only 0.34 pounds of oil per hour. Engines of even larger size are under construction, and it now seems certain that within the next few years oil motors will be applied to ocean ships of the very largest size.

Steam Railroads.

On steam railroads, at least in the United States, there is a growth in the size and weight of the individual unit, corresponding to the increase which we have noted under the head of Merchant Marine among the ocean steamships. Both for freight and passenger service the modern engines have attained proportions undreamed of only a few years ago. The Pennsylvania Railroad Company has recently completed a passenger engine for its heavy, fast, mountain service, with a total boiler heating surface of no less than 6,000 square feet. It is not so many years ago that 3,000 square feet of surface was considered extraordinary. A gratifying fact is the steady growth in the number and popularity of all-steel passenger cars. The Pennsylvania Railroad set a good example by building no more passenger cars of wood, and before long the whole of its service will be of steel construction. Other railroads are following suit. The steel car is one of the greatest protections to human lives and limbs in the event of derailment or collision. But with this increase in the weight of rolling stock comes the realization of the fact that the track is not equal to its work. Not only must rails be made heavier, but—and this is far more important—they must be made of a much higher grade of steel. The rail breakages of the past few months have increased in number and have proved frightfully disastrous. The remedy is to be found chiefly in a more careful casting of the ingots, taking all the time that is necessary to secure sound metal, and in the introduction of one or other of the successful methods of ingot casting, notably that of Hadfield, which have been developed abroad. This, with more careful work in the rolling mills, will make it possible to turn out a steel rail that will not be a cause of continual, heart-breaking anxiety to those who build and operate our railroads. Given perfectly sound and reliable rails, creosoted ties, tieplates of ample surface on every tie, and the replacement of the inefficient spike by the screw spike, and we shall have tracks over which our trains may be run at the highest speed with perfect safety. These changes, coupled with that "general stiffening of discipline," of which the railroad management have so much to say in these days, will go far to reduce our present appalling annual totals of killed and injured.

Astronomy

The most spectacular event of the year was the discovery on March 13th of a nova or new star by Enebo, an assiduous Norwegian observer of variable stars. When first seen it was a little above the fourth magnitude, but by March 16th it had sunk almost to the fifth. The spectrum of the new star presented the typical appearance of many novæ—broad bright and dark bands widely displaced, with this exception: Prof. Kuestner of Bonn found dark lines of uranium and radium emanation in the spectrum. The importance of that discovery can hardly be over-estimated, since it may help to shed some light on the moot question of the origin of novæ in general. One of the most important astronomical events was the recapture—if we may so speak—of a very remarkable asteroid on October 3rd, 1911, by Prof. Palisa of Vienna. All the asteroids move eastward, around the sun, but the eastward motion of all previously known planets (except Eros at perihelion) is slower than that of the earth, so that we leave them behind and they seem to move toward the west. The news of the discovery was spread abroad by telegraph, and on the following night another observation was secured by Palisa, and two by Techule at Copenhagen. Bad weather set in, the moon came along and made the sky too bright to see faint stars, and, after she had gone, the new planet was lost and could not be recovered. Mr. Haynes of the University of California, using certain very powerful methods of calculation, developed by Prof. Leuschner of that university, succeeded in getting an approximate orbit, which was published last April. Thanks to Haynes, the planet has been identified on a plate taken at Heidelberg in the middle of September and one exposed at Johannesburg on October 18th.

Dr. Slipher, the able assistant of Dr. Percival Lowell at Flagstaff, for the first time obtained evidence concerning the rotation of the planet Uranus. Spectroscopic observations show this to be a little over fifteen hours, the direction of motion being retrograde. A comet visible to the naked eye was discovered by Gale of Sydney, Australia, on the morning of September 9th. Its orbit proved to be nearly if not quite, parabolic in form and was remarkable chiefly for the fact that its plane was almost at right angles to that of the ecliptic. Its closest approach to the sun occurred on October 5th at a distance of 67,000,000 miles. A second comet was discovered by Schaumasse at Nice on October 18th. As soon as its orbit was roughly computed, it was seen that it was moving in a path very similar to that of a well known periodic comet—Tuttle's—which last appeared in 1899. But, according to the orbit then computed, this comet is not due to return until January, 1914. Fayet, a colleague of the discoverer of the comet on its present return, made a preliminary calculation of the motion of Tuttle's comet since 1899 and found that toward the end of 1900 it passed within 70,000,000 miles of Jupiter, whose attraction considerably modified its period, and accelerated its return by three months. The comet is of interest on account of its period—thirteen and a half years—intermediate between the numerous groups with periods varying from five to seven years and the longer periods, like that of Halley's comet, and also because of the high inclination of its orbit to the plane—fifty four and a half degrees. A third comet was discovered by Borrelly at Marseilles on November 2nd. An eclipse of the sun occurred on April 17th. The distance of the sun and moon happened to be in just such a ratio that the two bodies, as viewed from certain parts of the earth's surface appeared of exactly the same size.

There was a total eclipse of the sun on October 10th, visible in a small part of the southeastern United States as a partial eclipse just after sunrise. The trail of total obscuration began in the Pacific off the coast of Nicaragua crossed South America from one point in Ecuador, a little north of Quito, to one in Brazil a little south and west of Rio de Janeiro, after which the whole course was lost in the South Atlantic. The greatest observable duration of totality was about one minute and sixty seconds on the Brazilian Coast.

Miscellaneous Science

While there has been every sign of activity and successful advance in all branches of pure and applied science during the past year, we have no one particularly striking discovery to record. The field of molecular physics continues in its rapid development, to which especially Sir J. J. Thomson and Prof. Perrin have contributed so important a share. Special mention must be made, in this connection, of the recent work of Dr. Laue at Munich on the molecular structure of crystals, as revealed by Röntgen rays, another experimental substantiation, along a wholly new line, of the atomic theory.

In the domain of chemistry it appeared at one time as if the year 1912 might bring the realization of the commercial production of synthetic rubber. But it appears that we must have patience for yet a while before this important step is fully accomplished. The Eighth International Congress of Applied Chemistry brought a wealth of interesting material to light, yet there is no one particular paper which, for its historic significance, calls for special mention in this retrospect.

In biology perhaps the most remarkable work in hand is that for which the Nobel prize has been awarded to Dr. Carrell—on the survival of excised animal organs, and the growth of such tissues in vitro.

Science shows no signs of lagging, there has been a steady advance along the entire front, though perhaps we have only few achievements of fundamental novelty to record for 1912.

Obituary

The obituary of the year in so far as it relates to Science and Mechanics, contains such notable names as those of Lister, Melville, Rotch, Wilbur Wright, and Poincaré. To mention the name of Joseph Lister is to think of the untold blessings of antiseptic surgery, for he was undoubtedly the father of that most merciful art. Before Lister's day the mortality from major operations varied from 50 to 61 per cent, to-day it seldom exceeds 10 per cent. He was graduated in 1852 and from 1869 to 1877 he held the chair of Clinical Surgery in the University of Edinboro. Long before this incumbency, however, he had done much experimental work to prevent germinal infection of wounds. He used carbolic acid as a germicide and his first application of antisepsis was made in the treatment of compound fractures. To him we owe the practice of dressing wounds with lint, soaked in carbolic acid, and it was he who first covered wounds not with cotton, but with sterilized gauze. But for Lister's work the marvelous surgical operations of the present day would be absolutely impossible. In the death of Abbot Lawrence Rotch the scientific world lost its foremost amateur meteorologist. Rotch was a pioneer in atmospheric exploration, in company with Assman and deBort. Being possessed of an ample fortune and a cosmopolitan education, he elected to lead a life both scholarly and useful. He founded in 1885 his Blue Hill Observatory, where he developed the technique of the meteorological kite, which has been called the corner-stone of the twentieth century science of aerology or the exploration of the upper air. This observatory has formed a model for all others including that instituted by our own Government. The successful use of automatically recording instruments at Blue Hill so impressed General Hazen, the chief signal officer, that they were officially adopted and have been in use in Government stations throughout the country. Mr. Rotch conducted the first American researches with sounding balloons, and he was the first in this country to use the pilot balloon to determine wind velocity and direction aloft by means trigonometrical observations. Nowhere is the value of his work more fully appreciated than in the field of aeronautics, where its practical results will become increasingly manifest as the years go by. The death of Henri Poincaré meant the passing of a great mathematician and philosopher, who by many competent authorities was considered to have been the greatest mathematician of our day. In his literary work, and particularly in his three books, the "Value of Science," "Science and Hypothesis," and "Science and Method," there is to be found that clearness and charm of style which are so frequently found combined in the deepest thinkers of the scientific world. His greatest work was done in the application of mathematics to physics. In the death of Rear Admiral George W. Melville, the Navy lost one of its most distinguished officers. He is probably most widely known for his heroic efforts to save the remnants of the De Long party in the arctic regions, and this was followed up by able scientific work done in connection with his later arctic expeditions. As chief engineer of the United States Navy, he was successful in maintaining American marine engine practice abreast of that of the world. In the death of Wilbur Wright, America lost one of its most distinguished and successful inventors. At a time when the world at large and indeed the majority of the engineers and scientists who wished to solve the riddle of flight, were thoroughly discouraged and ready to believe that a successful man-carrying flying machine was inherently impossible, Wilbur Wright, in company with his brother, Orville, determined to gather up the many broken and separated threads of the investigation, piece them together and carry it on if possible to a practical solution. All the world knows how by making a short, half mile flight in a motor propelled man carrying machine they at last succeeded. The announcement of their success met with the usual incredulity. They returned to their little workshop, and in a few years time forced conviction upon an unwilling and astonished world. The universal high regard in which Wilbur Wright was held was due as much to his modesty and absolute sincerity as to the brilliant achievements which stand to his credit.

[The review of aviation and aeronautics will appear in our next issue.—EDITOR.]

A Parcels Post Tunnel Railway

Transporting Mail Automatically by a New System

[The advent of the Parcels Post will probably create a demand for means of transporting large numbers of parcels by some more expeditious and less easily interrupted method than the horse drawn vehicles or motor cars that must be relied upon for the present at least The following article describes one system which has been constructed for demonstration purposes —EDITOR.]

Placing a parcel in the car The space is sufficient to hold six ordinary mail sacks, or many Parcels Post articles.

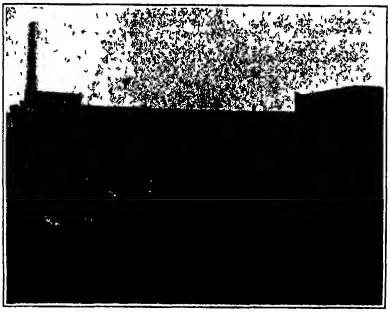
As the car stops the shoes are unlocked, and the car may be moved out of the way of the following one.

IN five of our big cities, namely New York Chicago Philadelphia Boston and St Louis, a large part of the first-class mail is transported between the post office and branch stations and railway stations through underground pneumatic tubes. These tubes are 8 inches in diameter and the letters tied up in small bundles, are dispatched in steel carriers which fit like a piston in the tube, and follow one another in rapid succession There are some routes—for example between railway stations, or between general post offices and railway stations where it is desirable to transmit the mail in sacks or pouches that are too large to be sent through the pneumatic tubes A commission has recently been appointed by the Postmaster General to investigate the feasibility and practicability of an underground tube or tunnel between the new post office located at the Pennsylvania Railroad Station, and the Grand Central Depot, in New York city which will be large enough to transport the mail in sacks.

An automatic tunnel railway has been designed that can be laid either underground or on the surface in which small cars are propelled by electric motors mounted on them, in much the same manner as ordinary trolley cars, but with this difference, that there is no attendant on the car to control it A demonstration plant of this new system has recently been erected on a vacant lot in Cambridge, Mass. opposite the site of the new Technology buildings by the company that operates the pneumatic mail tubes

It consists of a galvanized iron building 60 feet long for a station, a tunnel and track nearly a third of a mile in length that begins and ends in the building, and a car to run on the track Inside the station are located an electric generator controlling switches, instruments used in making experiments, space for loading and unloading cars, and means of switching the cars from the main track

The tunnel railway car is cylindrical in form, about 25 inches in diameter and 7 feet 3 inches long, large enough to hold an adult There is one supporting wheel and two guide wheels at each end.



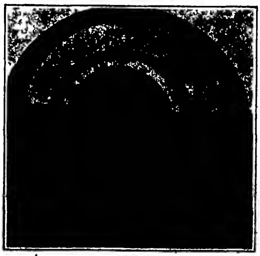
A demonstration plant of the new automatic railway tunnel system. It comprises a tunnel and track nearly one third of a mile long and begins and ends in the station in the background. Car in position on the track.

to sidings. Leading out of the building is a tunnel made of 30-inch diameter cast iron pipe, similar to ordinary water pipe. Four rails are laid inside of the pipe, one on the bottom to support the car, one on each side to keep it in an upright position and on insulated conductor rail on the top This pipe or tunnel is 234 feet in length and includes a bend of 90 degrees. The track extends beyond the pipe in a skeleton tunnel formed of cast iron hoops at intervals of three feet, to which the rails are attached. This skeleton construction is used for the rest of the distance around a rectangular space, terminating in the station Part of the way it is supported on trestle work to make an ascending and descending grade of 5 per cent. The total length of the track is 1,534 feet and includes four curves of 50 feet radius. No shorter curves or steeper grades would be required in underground lines for regular service At one point a short section of concrete tunnel has been constructed of elliptical cross-section 6 feet high and 7 feet wide to show how two tracks can be laid in a single tunnel In some places a single concrete tunnel is preferable to two cast iron pipes, and it has the further advantage of giving freer access to the tracks.

The car which runs through the tunnel on the 3 rail track is shown in the accompanying photographs. It is cylindrical in form about 25 inches in diameter and 7 feet 3 inches long The space for mail and parcels inside the car is 24 inches in diameter and 4 feet long sufficient for six ordinary mail sacks, and if used for parcels post would be ample for a large number of miscellaneous parcels. The opening through which the car is loaded and unloaded is closed by a double-hinged cover that can be opened from either side. There are one supporting wheel and two guide wheels at each end of the car The supporting wheels have double flanges, and one of them is connected through

(Concluded on page 18)

An automatic tunnel railway that can be laid underground or on the surface, in which cars are propelled by electric motors, in much the same way as ordinary trolley cars, but with this difference, that there is no attendant on the car to control it.



Four tracks are laid on the inside of the railway, one at bottom to support the car, one on each side to keep it upright, and a conductor rail on top.

Scientific Management for Scientists

"The Bridge." The Trust Idea Applied to Intellectual Production

By Professor Wilhelm Ostwald

[*WILHELM OSTWALD must be reckoned among the founders of the modern science of physical chemistry. As the director of the Physico-chemical Institute of the University of Leipzig he not only himself contributed a lion share toward the upbuilding of this science, but by personal encouragement, teaching and writing, he has done more than is probably realized by all but a few to assist in the making of such men as Arrhenius, Bredig and others. It will be remembered, too, that one of van't Hoff's principal publications appeared in an early issue of the Zeitschrift für physikalische Chemie, then newly founded by Ostwald. Of late years, since laying aside his professional duties Ostwald has devoted his main efforts to philosophical work and to the support and propaganda of movements relating to various phases of scientific and public activities.*—EDITOR.]

Within the last century or so the world has awakened to a realization of the fact that, of all the social activities of humanity, science in its broadest sense, is the most important. It is true that as yet the appreciation of this state of affairs has failed to find adequate expression in a practical way, and the so-called civilized nations are to-day spending incomparably more for the maintenance of barbarous military organizations than for the scientific development of problems relating to the culture of mankind, although the former are specifically destructive of energy and pernicious in their action, while only the latter work for energy concentration and upbuilding. The leading spirits of all nations, however, have long since come to a clear understanding of this situation, and accordingly we see numerous institutions, universities, academies, scientific societies, etc. engaged in energetic and effectual activity in the effort of extending the entire field of human knowledge to the utmost.

The phase of this field which has not as yet been satisfactorily organized is essentially that which relates to the character of the knowledge after which we are to strive. Through a perfectly natural process of historical evolution many still regard a mere knowledge of the past, a mere accumulation of facts, as real science, and only slowly, under the pressure of the exigencies of our day, the fact is gaining recognition that all science has one and but one purpose, viz., that of *predicting the future.* Hence every branch of knowledge which claims the right of cultivation by humanity at large, or by an individual nation, must, first of all, justify its existence and prove its claim to social support by demonstrating its social value—which consists in nothing more nor less than its capacity of forecasting the future, and thus influencing it in a direction favorable for humanity at large.

Thus, for example, as has been clearly shown in the development of medicine in the last few decades, it is now merely a matter of time, and especially of money, whether and to what extent great afflictions of the people, such as tuberculosis, can be exterminated, and humanity thus be freed from one of its direst plagues. The successful war waged against a number of febrile diseases by an investigation of their mode of propagation through the agency of mosquitoes has resulted in the opening up of great tracts of territory on our earth, which were hitherto uninhabitable owing to the prevalence of such diseases, and has thus greatly increased the total population which can find sustenance and be accommodated with some degree of comfort upon our globe. At an expenditure of a few millions of dollars it would be possible to solve in exactly the same manner greater and more difficult problems, and, I repeat it, it depends merely on our spirit of enterprise how soon and how successfully such work will be actually realized.

While the financial means for carrying out work which obviously and directly serves for the welfare of the community are obtainable with comparative ease more difficulty is experienced when the effort is made to engage assistance for some abstract scientific work, which can be applied only in the third or fourth instance to the direct amelioration of human conditions. But such science also deserves the most assiduous and careful attention. The question whether a given knowledge can or cannot serve for forecasting the future, need not be restricted to the inquiry whether such prophecy relates to possibilities of direct practical application. Every anticipation of the future may sooner or later become important. A very good example of this is the development of organic chemistry which originated in Germany in the hands of Liebig primarily as a matter of purely scientific research and which has since then made Germany the unquestioned peer in the world's chemical industry.

PROFESSOR WILHELM OSTWALD

We can therefore say—speaking very generally—that at the present day a great deal is being done for science. Indeed, at times it almost appears as if too much were being done, for, if we inquire from any worker in one of the large divisions of science about the present state of our knowledge in such field, the answer is almost invariably a complaint that it has become practically impossible for the individual to follow the total production in his science, which has grown to gigantic proportions. While in the first half of the last century one head, such as Berzelius, was capable of completely commanding the entire field of chemistry, so that he was in a position for many years to write his famous "Annual Report" (Jahresbericht) on the advances of chemistry, and to give an authoritative statement of the value of the researches covered, such an undertaking, comprising the whole province of chemistry, is, at the present day quite unthinkable for a single individual. Even the subdivisions, as organic chemistry or physiological chemistry have grown so vast, that there is probably no man living at the present day who can command such a division in the same way as years ago Berzelius covered the entire field.

What has been said of chemistry is equally true of the numerous other branches of science. Everywhere complaints are made by workers and investigators that it is becoming more and more difficult to obtain a complete survey even in a comparatively restricted field of the current scientific production of the day.

The conclusion in brief is that *at present the scientific production exceeds the human capacity for assimilating it.* The ratio which the production of new knowledge bears to our means of disseminating and utilizing the same has become modified to the detriment of the latter task. This is a perfectly natural phenomenon for the production of knowledge is a matter of such primary importance that it has received very predominant attention on the part of the most enlightened uplifters of humanity. It is only in our own day that the second problem has become more and more pressing in view of the conditions depicted above. It is true that in certain of the smaller subdivisions of human knowledge an inner technical organization for the purpose of effecting the assimilation in question has taken place. In particular to chemistry the debt is due on the part of the rest of the scientific world for the invention of the Annual Review by Berzelius, through which the total production of a year is brought together in orderly sequence and arranged in handy form for future reference. But this method of recapitulation is no longer sufficient with modern high speed of production and thus, for instance in the *Chemisches Zentralblatt* of the German Chemical Society we see an attempt to communicate to the world at large the current production with the minimum loss of time possible. Such abstracting is very widely developed in the field of chemistry and in other sciences also. The great chemical societies of all civilized nations have each organized a separate abstracting service which seeks to cover comprehensively the total scientific production of the world in the form of short abstracts.

It will be easily seen that this method is attended with great waste of energy. Not only are there three independent abstracting centers among English speaking nations—one controlled by the American Chemical Society, another by the English Chemical Society and a third in a certain measure by the Society of Chemical Industry—but in addition to these there are at least five or six abstracting agencies in the German language devoted partly to the entire field of chemistry and partly to large subdivisions thereof, in addition to these there are similar publications of the same character in French, Italian, Russian, etc. Every paper published is therefore abstracted independently at least ten times and in this way an immense waste of energy is incurred which is in no way inherent in the matter at issue but is purely the result of lack of organization.

What I have stated here from personal knowledge with regard to the lack of organization in chemical science, is seen again in precisely the same way in the other sciences. A few domains in which co-operation is particularly important, such as astronomy and meteorology, are considerably better organized in proportion to their special needs. These organizations are international, but are restricted to certain narrow fields of pure and applied science. Other international organizations, which theoretically cover the whole field of science, such as the Association of Academies, have not

yet acquired a form of activity which should insure for them co-operation with economy of energy in the entire field of science, so that here also the problem still remains to be solved

Now it so happens that at the present time, in an entirely different field, namely, that of finance, a process is going on which may be regarded as a model for the organization of science and intellectual work The recognition of the fact that competitive struggle is the most energy-destroying and impracticable of all methods by which opposing wills can be brought into equilibrium, is gaining a stronger and stronger foothold. In place of bitter competitive strife among related industries and commercial undertakings, we see going on everywhere the inverse process of the combination of analogous enterprises for joint collaboration and for the rational distribution of the several functions to such parts as are, through the general force of circumstances, best adapted to perform the same, or in other words, as are in a condition to carry them out with the highest efficiency in energy consumption

The process which we thus see going on in the world of economics must necessarily unfold itself also in that field in which the highest possessions of humanity are treated, namely, the field of intellectual labor The need has become urgent that the total work of this activity of the human race be so organized and brought into harmonious union that no energy be wasted Energy *is* wasted where one and the same piece of work is performed several times over, as we know is the case, for example, in the abstracting of current chemical literature, and energy is also wasted where each individual piece of work is not performed under the most favorable conditions with the best auxiliaries available at the present time. An organization of the world's intellectual work would therefore have to solve the problem of exerting a favorable influence in these two directions.

If, now we ask ourselves how such an organization could shape its activity, the answer is as follows The *highest* creative productions in science will have to be left as before to individual highly gifted heads and all that an organization can do here consists in placing the mechanical aids for such work at the disposal of those who are capable of carrying it out. In this direction a great deal has already been done, as was remarked above, both by private initiative and by governments Work of this character, then, cannot very well be organized At the other extreme, on the contrary, there is every possibility of organization The possibility of thus organizing that is to say, of establishing some uniform and simple plan, is given pre-eminently in the case of those portions of intellectual work which are simplest and most widely distributed, for the simpler a matter is, the more easily can it be made independent of the individuality of each worker and the more readily can it be replaced by, as it were, factory methods of production and a mechanical mode of procedure. With this point in view, then, an international institute was founded last year in Munich, under the name "Die Brücke" ("The Bridge") * which deliberately and positively follows the plan of undertaking the organization of scientific work, not from above downward, as hitherto, but from below upward, by, first of all, introducing uniformity and effecting a saving of energy consumption in those things which can be thus rendered uniform without prejudice to the main task itself Such are more particularly matters of detail relating to the technique of the production and use of publications and books. By far the greater part of science is, at the present day, recorded in the form of paper covered with writing or print, and consequently a practical and thoroughly efficient "*get up*" of this fundamental tool of all intellectual work represents a problem of fundamental importance

Thus, the establishment of a definite scientific scale of size for books and publications of every kind, has, for example, been one of the first tasks undertaken by "Die Brücke" If we reflect how very much easier all labor of writing and printing would be if it were carried out uniformly upon paper in a series of systematically well regulated sizes, how much less space would be taken up by books in our libraries if they all had the same height and breadth, how much easier the management and indexing of all collections of printed documents would be, had we not continually to contend with the differences in the sizes of the volumes, it will be seen that this seemingly trivial matter, in point of fact, lies at the base of all rational organization of scientific work.

The work of "Die Brücke" is not to be restricted to this. Part and parcel of this purely technical organization, which comprises, in addition to the work mentioned, a number of similar tasks, such as the preparation of copies, the cultivation of international language, etc is also the organization of the intellectual work already accomplished and of that still in progress, as regards its arrangement according to subject, author and institution. "Die Brücke" is planned as a central station, where any question which may be raised with respect to any field of intellectual work whatever finds either direct answer or else indirect, in the sense that the inquirer is advised as to the place where he can obtain sufficient information. Just like a telephone central, "Die Brücke" is intended to place every investigator in communication with every one of his fellow workers and to unite his field of work with every other field, and in this manner ultimately to establish a central for the entire unlimited field of intellectual work, by making use of which every person can automatically find his place in the great organism of the entire intellectual world, working with the minimum waste of energy

Within the last few years successful efforts have been made in America to introduce the idea of scientific management in all sorts of fields, so that we may expect with confidence to find there a responsive audience when we speak of the organization and systematization of the world's intellectual work. "Die Brücke" has only recently come into existence and is therefore still engaged with preliminary work in Germany, the place of its origin, but we believe that we can confidently assert that our first brother institution, which will work together with "Die Brücke," according to the same principles and with the same aims, will be opened in the United States, the energetic and determined population of which seems best adapted, not only to perceive the unlimited utility of this plan of organization, but also to secure for it a practical realization.

The Military Supremacy of the Air—II

By Theodore M R. von Keler

(Concluded from the SCIENTIFIC AMERICAN, December 28th, 1912, page 550)

WHILE France possessed a goodly number of airships of the Lebaudy and Clément Bayard type several years ago, the rapid development of the swift aeroplane placed the large airship in the background, and it was not until the Zeppelin successes that France awoke to the fact that it had allowed Germany not only to catch up in this particular field, but to set the pace for other nations to follow The need for large ships capable of staying in the air twelve hours or more at heights above 4,500 feet, and of traveling 500 to 600 kilometers without landing, was felt, and the new law provides for several new ships of not less than 8,000 cubic meters (282,516 cubic feet) During the year 1913, more ships are to be constructed, until the readily available aerial battleship fleet comprises twenty first-class up-to-date ships. Thereafter this number of ships is always to be kept ready for service, old types are to be constantly improved or displaced by new ones, similar to the programme followed in naval affairs.

In the report of Clément to the French Senate on the subject of airship construction, special emphasis is laid on the excellence of the rigid type The separate compartment idea is also advocated, as utilized in the Zeppelins, while the armament and observation platform of the Zeppelin ships are recommended for use on the new French ships now building.

It is but natural that such extensive plans for increases in the size and number of the ships should demand similar plans for the housing, transportation and filling of these giant aircraft The big fortresses, Verdun, Toul, Epinal and Belfort are fully equipped as aerial "harbors," while Maubeuge, Reims, Chalons-sur Marne, Chalais-Meudon and La Motte-Breuil are being prepared for the reception of airships.

The great maneuvers of last fall have shown that aeroplanes, in order to be of real value to an army, must be capable of rising from the ground anywhere without the necessity of depending on a permanent base. The first requirement is naturally a ready means of taking the machines apart for transportation, this was one of the tests of army aeroplanes last year, and has been made more rigid this year It is now required that aeroplanes can be taken from the motor truck, put together and made ready for flight in the space of ten minutes. Specially designed motor cars accompany the aviation companies, carrying spare parts, supplies, wireless outfits and even complete machines in "knock-down" condition.

In order to be absolutely independent of road conditions in a hostile country, some of the aviation companies will be attached to cavalry and artillery divisions, and the horses of the latter will be utilized in pulling the aeroplanes cross-country, where it is desired to save fuel and keep the presence of the machines hidden from the enemy

What type of flying machine is most suited to military work, is still a much mooted question The rapid development of the various types renders a final selection impossible at the present time, but two or three-seated machines are preferred to singles. The ministry, quite sensibly, contends that the handling of the aeroplane itself is at present such a difficult and comparatively complicated matter, that no opportunity is left to the aviator to take proper heed of the ground below him, to make sketches or notes, or to receive and send wireless messages. To take care of the most important duties of the military aviator, an observer should take a seat in the machine, whose sole occupation would be the reconnoitering of the enemy's position and an examination of the territory over which the machine flies. For this work only the older, more experienced officers of the general staff are to be used, leaving the youthful lieutenants in charge of the flying.

An aeronautic section of the French army consists of eight aeroplanes and fourteen motor cars, divided into four columns. The first column has two monoplanes with single seats, for fast superficial observation and delivery of orders, the second has two biplanes with double seats, the third has aeroplanes with two and three seats, while the fourth, or reserve section has one single and one double-seated machine. Each section comprises seven pilots and fifty non-commissioned officers and men.

Besides these "regular" aeronautic sections there are a number of especially fast and powerful machines, capable of carrying two observers each in addition to the pilots, for emergency work. These machines are directly under the orders of the commanding general, are kept near his headquarters, and are able to cover a territory of not less than 100 miles radius.

At the beginning of this year France could mobilize thirteen sections with over 200 available aeroplanes, while before the end of this year no less than 334 machines (30 triples, 160 doubles and 144 singles), valued at $1,000,000, operated by 286 military pilots and 210 observation officers, will be in use. The average life of an aeroplane is fixed at two years and the operating cost $000 annually for each machine.

During the great artillery maneuvers in March of this year, aeroplanes were used in determining the firing efficiency of the guns. Six Blériot single-seated monoplanes, four Farman double-seated biplanes, and three triple-seated Bréguet machines were used in the tests with remarkable effect. While the officers are naturally reticent about the exact results obtained, it has been positively stated that any hostile battery could be destroyed in a few minutes by means of the aeroplane observations, provided it was located within shooting distance Particularly the aeroplanes with two and three seats did good service, and monoplanes with single seats are not likely to be used in this work.

France pays special attention at present to inventions designed to throw or drop explosives from soaring aeroplanes on moving trains, on bridges, powder magazines, etc It is, of course, self-evident that the first hostile step on the part of Germany would immediately be followed by a descent of a flock of French aeroplanes upon frontier towns and fortresses. Bridges would be destroyed, railroad tracks demolished and magazines exploded, thereby greatly hampering the German advance after mobilization. Military aviators do not place much value on machine guns designed for shooting into the air, and less on rifles installed on the aeroplanes for horizontal attack. It appears to be the general opinion among them that the mastery of the air must be fought in the air, and that aerial battles will be won by skill in operating the machines and high speed. According to their idea, an aeroplane would have to soar over or above its enemy and then *drop* an explosive on it. To do this, the machine must be high-powered, swift and controlled by fearless expert pilots. And that these considerations have passed the romance stage, and are hard facts of the present day—the next big continental war will show Germany is watching the activity of the French with eagle eyes, and the successors of Moltke and Bismarck are not likely to permit themselves to be left in the rear in the fight for control of the air

LIST OF MILITARY AND PRIVATE MONOPLANES AND BIPLANES AND DIRIGIBLES.

	Military Monoplanes.	Military Biplanes.	Private.	Dirigibles.
France	144	190	500	15
Germany	82	57	150	20
Russia	50	64	50	10
Great Britain	16	36	120	8
Italy	26	16	50	7
Austria	25	5	25	4
United States		12		

Arranged in the order of their relative strength up to and including July, 1912; additional machines ordered for delivery in 1913 have been included in this table.

High Speed on No. 20 Crossovers

To the Editor of the SCIENTIFIC AMERICAN

After following very closely the controversy in your columns precipitated by Vice-President McHenry, and the complete knocking out by you of every leg which he attempted to stand on in his argument, my attention is drawn to the inclosed half-page advertisement in the *Springfield Republican* to-day, which I presume is being published extensively in the prominent papers through the eastern part of the country, as a large amount of the stockholders' money is being squandered at the present time in this manner

The point to which I wish to call your attention and ask for technical information on is in the first paragraph, which has been marked, as in your argument the statement was made that the No 20 crossovers between New York and Philadelphia daily cared for the trains at full speed As this advertisement purports to be the second time that the "truth has been told," it would appear as though a misstatement was made, as, without further knowledge, I should much prefer to tie to statements which you made regarding the daily operations on the Pennsylvania. H E SCHMUCK

Springfield, Mass.

[The overturning tendencies of a No. 10 crossover are nearly four times as great as those of a No 20 The Pennsylvania expresses daily run through No. 20 crossover at far higher speeds than the slow order speed of 35 miles an hour, and they do so without risk.—EDITOR.]

The Reindeer in Alaska

To the Editor of the SCIENTIFIC AMERICAN

The note about the Alaskan reindeer herds in the issue of August 10th, 1912, calls for some statement of facts as commonly but accurately known throughout interior Alaska. Any success resulting from the introduction of the reindeer into Alaska has been confined entirely to narrow strips of land bordering the oceans, and capable of supporting but a small population A few, a very few, people have been able to make a living with them. These cases have been quoted repeatedly On the other hand, continued and persistent attempts throughout the interior have been expensive failures, because of the scarcity of the variety of moss which the reindeer requires. Mere moss can be found almost anywhere, but the only kind upon which reindeer can live is found only occasionally Consequently, as a draft animal, it is impracticable for the greater part of the country, since long detours must be made in search of food Such detours are expensive and often unsuccessful I recall one instance, happening at Anirk, in the winter of 1908 to 1909 The superintendent of schools for the Government came in one day with several reindeer, drivers, etc They had hunted for suitable moss in vain, and now had to hire native guides to lead the way to the nearest patch, some twelve miles away Arrived there, they had to shovel snow several hours in order to make it possible for the reindeer to reach their food The superintendent was at the time on his way to remove the small herd at Holy Cross, which had been a great expense to the Government during that winter, requiring the continual service of between thirty and forty men, whose main duty was to shovel snow off the moss for the herd.

Your article states that "it is expected that the exportation of reindeer meat will soon become an important industry " This is absurd, as can plainly be seen from the fact that thousands of beeves, as well as sheep and poultry, are annually imported to supply the meat needed There is a continuous but unfilled demand for caribou and reindeer meat. The price of meat here is far higher than in the States, so that a surplus of reindeer meat from the coast herds could much more profitably be shipped here than elsewhere. As it is, the Government itself buys hundreds of beeves to supply meat for the army posts and for the Signal Corps men stationed along the telegraph line.

So it is that, both as a draft animal and as a meat producer, the reindeer has proven a failure in Alaska except in a few localities. For unfrequented trails, the Alaskan dog (Husky or Walamute) is the peerless standby On the mail trails, hard packed and continually used, stage coaches and horse-drawn "double-ender" sleds prevail At each station of the Signal Corps will be found a horse or dogs, according to the nature of the surrounding trails. Meat is shipped in hundred-ton lots or driven in from Cordova or Valdez in herds of hundreds. Practically all reindeer herds have been withdrawn from the interior, since careful attempts have shown that their care and keep far exceeded the returns. In view of these facts, counteracting the limited success in a few places, it is little more than a quibble to make such ambitious claims for the Alaskan reindeer herds.

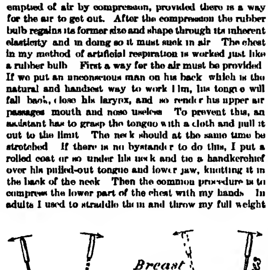
Artificial Respiration With a "Lemon Squeezer"

To the Editor of the SCIENTIFIC AMERICAN

Lately a great deal of interest has been shown in resuscitation from electric shock. We live in an age of electricity, and electric accidents are getting to be of every-day occurrence in most places, and, what counts more with the electric companies we have now a national employers' liability law as well as similar laws in some of the States. These laws take their pet defenses away from the companies and lay them open for damages.

Everybody seems to agree that in artificial respiration must be placed our greatest hope in such cases, but how this is to be done there is a difference of opinion The thorax or chest resembles a rubber bulb like those we use on atomizers Now, we all agree that such a bulb can be emptied of air by compression, provided there is a way for the air to get out. After the compression the rubber bulb regains its former size and shape through its inherent elasticity and in doing so it must suck in air The chest in my method of artificial respiration is worked just like a rubber bulb First a way for the air must be provided If we put an unconscious man on his back which is the natural and handiest way to work him, his tongue will fall back, close his larynx, and so render his upper air passages mouth and nose useless To prevent this, an assistant has to grasp the tongue with a cloth and pull it out to the limit The neck should at the same time be stretched If there is no bystander to do this, I put a rolled coat or so under his neck and tie a handkerchief over his pulled-out tongue and lower jaw, knotting it in the back of the neck Then the common procedure is to compress the lower part of the chest with my hands In adults I used to straddle them and throw my full weight



Method of using the "lemon squeezer" I, active inspiration, II, deepest unassisted expiration, III, deepest expiration assisted by levers.

on them—175 pounds. There is no doubt in my mind that this is the most efficient method of artificial respiration, but it is so tiring for the operator that it becomes necessary to take turns at compressing, especially since artificial respiration must be kept up for a long time in all such cases.

Of all the mechanical appliances the lever is the simplest and most efficient, and it occurred to me that a modified lemon squeezer would work well on the chest So I took two boards for levers, and connected them at one end with a cord for a fulcrum Two boards, size about 19 by 3 by ¼ inches, will do I shape them with my pocket knife like flat Indian clubs, drill a hole through one end of each, run a string through the hole in one lever keep the string from pulling through by a knot, and am ready for business

When anybody is shocked around electric work, he should be put flat on his back, his neck stretched, his tongue pulled out to the limit, and his chest compressed with the levers or "lung crutches" as I call them They are simply attached as handles to the chest, and the chest worked like bellows The operator (in electric works the foreman should be so trained) slips the cord fulcrum under the man's chest, runs it through the hole in the other lever, adjusts it with a slip knot to the size of the patient so that the cord is taut behind the back and the handles not quite parallel but a little divergent in front. Then he compresses the chest slowly and easily, keeping time with his own breathing This he keeps up till a physician arrives and takes charge

Such artificial respiration is, as far as the change of air into and out of the lungs is concerned, similar to natural respiration, but is not equal to it. Anyhow, it is the best we can do till a physician arrives and tries to restore the action of the heart by other means.

Cambria, Cal. A. C. MULLER, M D

Risks in Straightening Rails

To the Editor of the SCIENTIFIC AMERICAN

Some few years ago I visited a large mill where railroad rails were being made The person acting as guide showed me all of the various manipulations, and in the end I saw them being made straight by a couple of workmen The process consisted of sighting along the rail, which was shifted back and forth under a press which was thrown in and out of action as the various kinks and bends were subjected to the pressure to straighten them

As I stood there interested in the work I saw two rails snap under the pressure exerted Having noticed a number of articles in the SCIENTIFIC AMERICAN on rail failures it occurred to me that possibly not a few of these failures might be traced to a small incomplete fracture caused at the time of straightening developing into a complete one I would not attempt to offer any suggestion as to a better way to straighten a rail, but surely any act which would break a rail could develop a crack which might develop into a complete fracture with disastrous results

Do you not believe that a careful examination along these lines would result in an explanation of why an apparently sound rail suddenly goes to pieces?

Nephi, Utah H G GOULD

[Our correspondent draws attention to a practice which has been criticised as liable to do permanent injury to a rail Cold straightening is undesirable to say the least the rails should never be straightened when they are below a certain fixed temperature —EDITOR]

The Transmutation of the Elements

To the Editor of the SCIENTIFIC AMERICAN

The interesting article which appeared in the August 24th issue of your valuable paper, "Can the Baser Metals be Changed to Gold?" attracted especially my attention because closely following an article where the same argument is masterly treated by Prof I Soddy of Glasgow University

Let me consider two possible sides of the transmutation problem, viz transmutation from light to heavier atomic weight elements, and transmutation from heavy to lighter atomic weight elements

The first side of the problem offers enormous difficulties and is obviously unsolved

The latter from your writer's point of view, seems to be solved by Sir W Ramsay's and Cameron's experiments

Mr Rutherford's criticism is reported and I will add that of Mr Soddy who clearly states in the article referred to that The energy of sub-atomic changes is thus of the order of a million times greater than the energy of ordinary chemical or molecular changes The energy evolved from the disintegration of a single atom is detectable by radioactive methods, whereas a million million atoms of any non-radioactive element is a quite undetectable quantity even with the spectroscope For this reason the identity of the final non-radioactive product of the whole sequence of changes still remains uncertain "

As a matter of fact, Mr Soddy is referring here to radioactive series disintegrations, not to artificially produced transmutation but he next points out that "The fact that it has been found quite impossible even by the most powerful agencies known to alter artificially the rate at which a radioactive substance is changing either to retard or to accelerate it, is obviously the corollary to the well-known impossibility of artificially transmuting one element into another "

It seemed to me necessary to note this discordance in judgments for the proper comprehension of the importance of transmutation that is going to take the preponderant place among the big problems of modern science, both chemical and physical.

The Modern Automobile Torpedo

The Story of a Great Invention

By Robert G. Skerrett

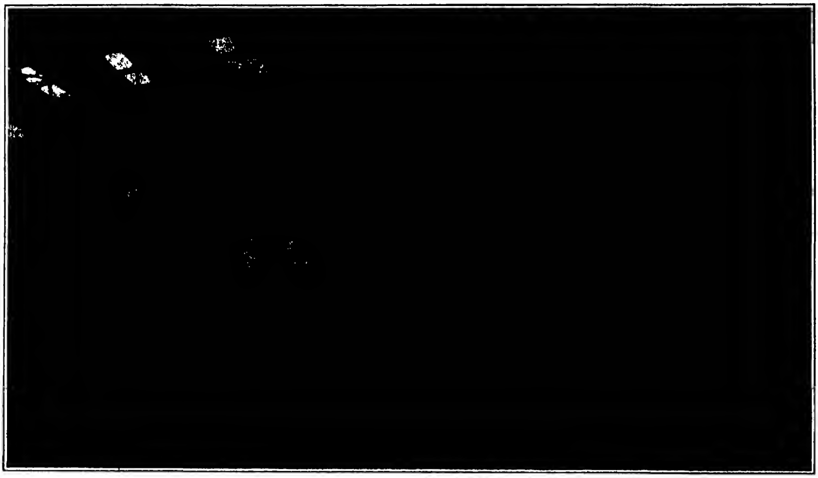
THE modern automobile torpedo so far as its inception is concerned is forty seven years old In 1864 Capt Lupuis of the Austrian Navy realizing the potential destructive powers of a torpedo capable of self propulsion conceived a type of miniature fire-ship or floating torpedo which could be directed from a fixed base by guiding lines Capt Lupuis proposed to propel his torpedo by means of clockwork or steam, but he had not personally the mechanical knowledge needful for the proper development of his weapon At that time Mr Whitehead, an Englishman and a man of exceptional mechanical skill was in charge of an engineering plant at Fiume, and to him Capt Lupuis turned for assistance The net result of the association was the awakening of Mr Whitehead to the field thus offered to engineering cunning Abandoning Capt. Lupuis scheme entirely Mr Whitehead set about devising a torpedo capable of self propulsion and self-direction—after once being started on its way—which, unlike the crude surface affair of Capt. Lupuis, should be able to run under water and safe from gun fire

financial position to obtain exclusive rights to the invention

From the modest 14-inch torpedo of 1864, with its limited range and speed, we have reached to-day a weapon weighing more than 1,600 pounds and capable of covering ranges up to 7,000 yards—traversing this distance in the remarkably short period of less than seven minutes. This particular torpedo is the invention of Lieut. Hardcastle of the British Navy In our own service we do not claim the same long range—4,000 yards being the maximum upon which we now place a military value, and the remaining speed at the end of this run is in the neighborhood of 28 knots. The explosive charge of the present-day automobile torpedo varies from 140 to 250 pounds of gun-cotton. The destructive force of a blow of this sort has been amply demonstrated recently by practical tests against the under water bodies of fighting ships. To-day, the builder of battleships can hope only to restrict the area of under water damage by subdividing his ship below the waterline into numerous water tight compartments. One torpedo will probably not be able to sink a dread

the value of the gyroscope, however, other minds promptly set about improving this instrument of lateral guidance. To begin with, the adoption of ball-bearings, nicer balancing, and the refining of various moving parts made it possible to lengthen the directive period of the gyroscope as well as to increase its sensitiveness—thus insuring a more reliable run and a speedier one by flattening the sinuous course The next developments introduced an air-impulse, turbine-driven gyroscope, and then an electrically-driven Obry followed. These have done away with the shock of the original spring impulse and have naturally greatly increased the directive value of the gear, besides making it possible to fire the torpedo from a broadside and cause it to swing automatically through an angle of 90 degrees toward a target dead ahead. From a weapon that was a menace to friend and foe alike, the installing of the gyroscope has revolutionized the automobile torpedo, making it under some conditions even more certain of hitting its mark than that possible with the biggest of our modern guns.

For years the wonderfully compact and efficient



Sweating in the ends of the air flask or "middle body" of a torpedo.

No 1 is the forebody or head of the torpedo 2 is the "middle body" or air flask 3 is the after body of the torpedo.

THE MODERN AUTOMOBILE TORPEDO

Some time in 1864 Mr Whitehead built in secret his first torpedo This weapon was a relatively modest effort having a diameter of 14 inches, weighing but 300 pounds, and carrying a charge of but 18 pounds of dynamite The motive power was compressed air stowed at a maximum pressure of 700 pounds per square inch and the torpedo was capable of making about 6 knots an hour for a short distance As soon as this torpedo was subjected to test in the water, Mr Whitehead was brought face to face with some of the harder problems of his undertaking. One of these was the task of properly controlling the submerged running Instead of keeping at a uniform depth the torpedo divided its time uncertainly between the surface and the waterbed, and it was seemingly impossible to keep it within the desired bounds. After four years of patient experimenting Mr Whitehead evolved his "balance-chamber"—for years guarded by every effort to keep it secret—by means of which the submergence of the torpedo became automatic the movement of a pendulum combined with hydrostatic pressure serving to actuate certain controlling mechanisms which, in their turn operated the diving rudders The Austrian government was the first to give official recognition to Mr Whitehead's work but was not in a

nought but it will be likely to so impair her military efficiency as to make her an easy mark for deliberate annihilation either by gun-fire or further torpedo attack.

Only a few years ago, comparatively speaking, the lateral course of the torpedo was decidedly uncertain, to put it mildly The range and speed had been greatly improved, but the torpedo still had a way of departing suddenly and mysteriously from its intended course—sometimes coming back at the vessel from which it was sent to the no small dismay of all hands. This was not a pleasant thing to contemplate in time of war when the head of the weapon would be loaded with its violently destructive charge. At this critical stage in the history of the torpedo, the Obry gear was invented. Briefly, the Obry gear consisted of a gyroscope placed within the torpedo and so connected by intermediate power mechanisms with the directive rudders that the weapon could be held to a fairly straight course or, more properly, to a sinuous one consisting of a series of flattened curves alternating from right to left. The original Obry gear had a spring impulse, its directive force rapidly diminishing from the instant of starting, and it became quite useless after the torpedo had run something over a thousand yards. Realizing

three-cylinder Brotherhood engine was the best available motor for the automobile torpedo, but even with its progressive developments it had the inherent limitations or drawbacks of the reciprocating engine, and it was only logical that the torpedo builder should cast about him for a motor capable of utilizing still better the power stored in the air flask. The turbine was the natural solution of the difficulty

All the while that the torpedo was improving in military value, the range of modern guns on shipboard was likewise undergoing substantial increment—making it possible for ships to fight at greater distances, and the torpedo expert realized, despite all that had been done to make his weapon more effective, that both the range and speed of the torpedo must be further increased if it were to meet properly the changed conditions. This was a staggering realization, because there were difficulties in the way of making a larger torpedo susceptible of easy handling, and it was not practicable to add much either to the capacity of the air flask or to the pressure of the energy stored therein. At this critical stage, American inventive skill found a way to surmount the obstacle. Mr Frank M. Leavitt, of the E. W. Bliss Company, made the starting proposal to heat the air stored in the flask, and thus to

cause its expansion and multiply its propulsive capacity. The first American development of the super heater for this purpose consisted of means by which alcohol could be burned within the air flask—the heated air passing thence through the valve system to the engine or turbine and, while still relatively warm passing outboard through the exhaust. Apart from propulsive advantages, superheating obviated another objectionable feature of the older system in which the changes of temperature were so great—due to the rapid expansion of the compressed air—that the ex haust was frequently far below the freezing point. This caused the lubricants to congeal and, in turn impaired the action of moving parts. The British development of the superheater omitted the alcohol flame from within the air flask and put it between the reducing valve and the motor. This was an advantage in some ways. It did not require the heated air to pass through the delicate valve system, it fed into the engine the air at its most efficient temperature, and it made possible a nicer control of the pressure at the during the entire run of the torpedo as he first did, he, too, heats the impulse supply outside and between the reducing valve and the turbine, but, in order to make use of more of the stored air than possible heretofore he causes the ignition of an alcohol flame inside of the flask toward the latter part of the run. By this means he is able to use to good effect 174 pounds of the original 191 pounds of the compressed air—thus increasing the range and the maintenance of higher speeds throughout the longer run.

Without giving away state secrets, the following table will show what the superheater has made possible in the case of an 18-inch torpedo. These figures are very instructive.

Speed in Knots.	Air Unheated	Air Heated
At 1 000 yards	35	44
At 1 500 yards	30	40
At 2,000 yards	28 25	38
At 3 000 yards	23-24	32
At 1 000 yards	18 20	28

called Calaminæ (i e, 'made of reeds''), in Lydia, which were not only driven by the wind but could be pushed about from place to place with poles.

Floating gardens—some natural and some artificial—have flourished in many parts of the world from early times. They are particularly advantageous in regions exposed to floods where a garden planted on *terra firma* would be ruined by these occurrences, while the floating garden is undisturbed by the rise of the waters. The famous floating gardens of Kashmir are a case in point.

The lake of Xochimilco, near the city of Mexico, is nearly covered with floating gardens called *chinampas* on which are raised vegetables and flowers for the city markets. They are formed of floating masses of water plants covered with soil and secured by poplar stakes. The latter take root and surround the islands with living hedges.

Among the largest of natural floating islands are those formed by tangled masses of trees and brush wood carried down by great rivers. On the Mississippi

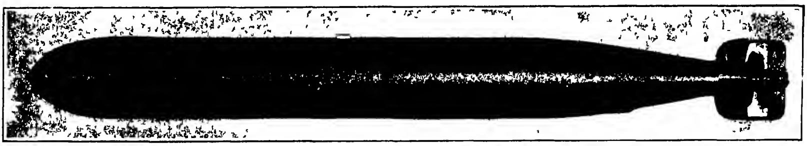
Ericsson's automobile torpedo of the 70's, built in this country, and tested at the United States Naval Torpedo Station at Newport.

This dirigible torpedo was designed to rival the Whitehead and the Lay torpedoes. It never survived the experimental stage. It was driven by compressed air.



One of the latest types of the Bliss-Leavitt torpedoes, showing the three separate sections of the torpedo in their assembled condition ready for service.

THE MODERN AUTOMOBILE TORPEDO

engine or turbine. However, like all good things, it had a drawback from a military point of view. When the air flask of one of our torpedoes is fully charged, the actual weight of that compressed air amounts to something like 191 pounds. The reducing valve, which regulates the pressure and supply of air to the motor—standing sentinel between the air flask and the propulsive mechanism—is designed to maintain a feed pressure of 300 pounds for the turbine impulse. When the pressure in the air flask approaches 300 pounds, the run of the torpedo is substantially at an end so far as its useful military speed is concerned. As the air in the air flask expands due to its gradual escape to feed the motor, the temperature is lowered sometimes even to below zero, and this remaining air is incapable of expelling itself from the flask for the purpose of effecting the propulsion of the torpedo. It has been found that when the superheater is outside of the air flask, of the total weight of 191 pounds of stored energy, not more than about 148 pounds are utilized. Again Mr Leavitt's ingenuity has supplied a remedy. Instead of heating the air within the flask

This article has reviewed only the more startling features of development in the so-called Whitehead automobile torpedo, but it must not be imagined that there have not been numerous other directions in which the weapon has been modified and bettered to overcome the cunning of the defense. These, however, contributing as they do to improve effectiveness and precision of action in one direction or another, are matters of detail which cannot be touched upon within the space of this contribution—interesting as they undoubtedly are.

Floating Islands

THE imagination of man has always been impressed by floating islands. In ancient times such islands were regarded with superstitious reverence, and the romantic story of Delos—the natal isle of Apollo and Artemis—is but one of many cases recorded in classical literature of vagrant islands in the sea. Pliny says that in the lake of Vadimonis there is a dark wood which is never seen in the same place for a day and a night together, and he describes the islands

and its tributaries these islands are known as "rafts." One of the most remarkable of these rafts began forming in the Atchafalaya, one of the lower arms of the Mississippi in 1778, and gradually increased until by 1816 it had extended to 10 miles in length, over 600 feet in width, and 8 feet in depth. Although it rose and fell with the water it was solid enough to support the growth of trees, some of which were 60 feet in height. This vast obstruction was finally removed by the State of Louisiana at great expense. The work began in 1835 and lasted four years. In more recent times a great raft in the Red River completely blocked the channel for 45 miles, until it was removed by the National Government.

Where a mat of vegetation borders the seashore the action of waves sometimes breaks off large islands. This was probably the origin of a remarkable floating island which was first seen in the Atlantic Ocean about 400 miles east of the New Jersey coast in July, 1892. Its area was about 9 000 square feet and it bore trees 30 feet in height. When again seen in the following September it had traveled over 1 000 miles.

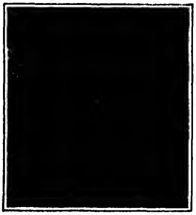
Turntable for Cars

IN the majority of garages there is very little room for the easy maneuvering of automobiles and a great deal of time is wasted in trying to turn a car about, particularly if it has to make a right angle turn to reach the elevator which will carry it to the shop. The accompanying picture shows a special form of turn table adapted to overcome the necessity of tedious maneuvering. The turntable is similar to that used for locomotives. It may be rotated by a single man by using a bar to engage any one of the several small holes in the outer edge of the table. The table itself is built of reinforced concrete and hence is proof against water and fire. The diameter of the table here shown is fourteen feet, so that it will take the largest touring car. It has been found of great convenience when adjustments or repairs must be made for the car can be swung around without any trouble to the best position to obtain all the available light.

Readers are invited to contribute photographs of novel and curious objects, unique occurrences and ingenious contrivances. Such as are found available will be paid for promptly.

An automobile turn-table for garages.

The original cave in Arizona.

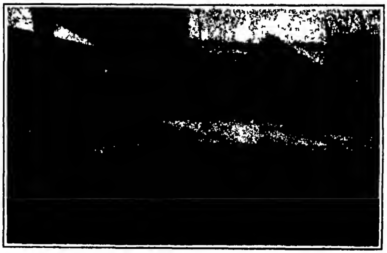


Reconstructing the cave in New York.

New York's Cave of Stalactites

ONE of the most noteworthy forthcoming exhibits in the Mineral Hall, at the Museum of Natural History, New York, will be the representation of a beautiful cave of stalactites and stalagmites. This will be a reproduction of almost an entire cavern recently discovered in the Copper Queen Mine, at Bisbee, Arizona. Here, a quarter of a mile below the surface, during the mining operations of blasting for copper, a spacious chamber was uncovered containing a series of terrace like grottoes adorned with a wealth of magnificent and many-colored stalactites and stalagmites. Dr. Douglas and the mining company placed the find at the disposal of the museum. Dr. Edmund Otis Hovey, Curator of Geology and Invertebrate Paleontology, with three assistants visited Bisbee to collect and bring back the original material so as to form an exact reproduction of the Arizona cave. A half a hundred boxes, containing the choicest formations from the walls, floors, ceilings, etc., were brought back. They weighed from one pound to nine hundred. The delicate task of setting up the pieces in the cave at the museum is being executed by Mr. William Peters, artist of the museum staff, who accompanied the expedition to Arizona.

A steel frame 12 feet high by 8 feet wide forms the outside of the cave, which will be covered with limestone blocks, taken from the mountain under which the cave was found. These wonderful formations of stalactites and stalagmites are made through the evaporation of percolating waters. The most striking feature of the reconstructed cave will be a stalagmite 3 feet in diameter and 3½ feet high, of a beautiful green color, and weighing about 900 pounds. This stalagmite is remarkable on account of the radiating clusters of pointed calcite crystals thickly set all over it but diminishing in size from the bottom of the column upward.



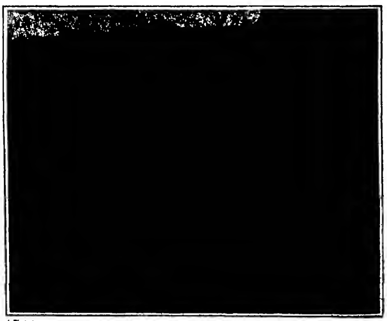
A rotating ice disk, naturally formed.

Electricity and Diet

SCIENTISTS have been looking for some method of replacing the multiple aliments which are needed to keep up the human body by food in a concentrated state, so that it could be absorbed with less fatigue. On the other hand a French scientist, Prof. Bergonié, claims that electricity will solve the problem. We have already mentioned some results which he obtained in this direction, according to the account presented by him to the Science Advancement Congress. Since then he has continued his researches and arrived at results which have almost a sensational character. Before this he simply proposed the idea that electricity could be made to replace food, that is by adding to the heat energy absorbed by the body, so that less food need be taken into the system. At present he is making actual experiments which appear to prove this conclusively according to his communication made to the Academy of Sciences. The experiments were made during the last few months at his laboratory at the Bordeaux University and fully confirmed his theories on the subject. His method, known as "diathermy," or application of low tension and high frequency currents to the human body, is able to make up for a part of the alimentation of the system by furnishing a large amount of heat to the body, instead of producing the heat from food materials which need to be consumed or indeed burned in the system, this giving rise to overwork of the physiological organs of the body. Such electric currents, as Prof. Bergonié says, will pass through the body without causing the least feeling, and with a current of 2 to 3 amperes strength and a voltage of 1,000 to 2,500 volts per hour about 1,000 calories of heat can be furnished per hour, this being over one third of the daily food ration. The following test will bring out the remarkable results which can be obtained by this method. He applied the electric treatment to a man 5 feet 10 inches high, whose weight before the treatment was only 110 pounds. The patient ate a great deal of animal food, but was in very bad condition, as he could not walk over 300 feet without needing aid. He was unable to work and was very sensitive to cold. After a series of treatments of 40-minute duration by the electric method, this corresponding to an absorption of heat equal to about 1,700 calories each time, the patient began to improve rapidly, and at the end of the treatment he gained considerably in weight. In fact, he then weighed as much as 140 pounds, which makes a gain of about 30 pounds. Dr. Bergonié states that the patient can now walk for hours without fatigue, and his physical vigor is restored to the normal. He is able to stand all degrees of heat and cold, and his general appearance is very good. The author considers that the time is not far distant when all troubles due to insufficient nutrition will disappear under a series of electrical treatments by high frequency currents according to the general method of M. d'Arsonval.

A Frozen Whirlpool

WE have received from a reader in Schenectady, New York, the accompanying photograph of a most unusual ice phenomenon. As the result of rotary currents in a mill pond, a large circular piece of ice nearly six feet in diameter was formed and kept separate from the main body of ice, owing to its continuous motion. The disk was almost a perfect circle, and moved slowly from left to right. This phenomenon occurred last winter. The unusual condition continued for several days until the ice had obtained a thickness of nearly two inches.



I. Illustration.

Statue of Marcus Aurelius removed from his horse for repairs.

Marcus Aurelius Unhorsed

THE noble statue of Marcus Aurelius in the Capitol Square of Rome has suffered severely from the ravages of time. Recently it was found that the precious bronze was urgently in need of repairs. The only thing to do was to remove the Emperor from his horse, and take him to the museum of the Capitol, where the rents in his garments and the scars on his limbs could receive proper scientific treatment. A scaffold was built over the statue and the Emperor was firmly bound by the legs and chest and then lifted from his horse by means of suitable tackle. Our illustration pictures him as he is being lifted and shows that even in this trying position he was not lacking in stoic gravity. While the Emperor was undergoing repairs at the museum his horse was completely boxed in by a temporary wooden shack. When the figure was removed from the horse there was considerable agitation on the part of a faction of young Italians who were anxious to have him replaced by a statue of Cæsar. Fortunately for the memory of the great Marcus Aurelius, this agitation was unheeded by the authorities.

Power of a Microscope

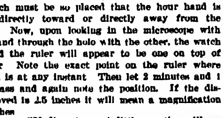
By C. W. Nieman

AMATEURS who have a microscope miss a great deal of the pleasure and interest to be derived from its use unless they are able to find the magnifying power of their instrument and to measure objects with which they are working. It is surprising how much more intimate an acquaintance with an animalcule or portion of an insect is obtained if we are able to say that it is 3/1,000 inch in diameter, or whatever else its dimensions may be.

In order to measure objects under the microscope it is first necessary to find its magnifying power, or, in case the instrument has several objectives and eye-pieces and the tube can be changed in length, to find the magnifying power under the various conditions in which it is used. All the methods the writer has seen involve the use of an object of known length which can be observed under the microscope. This usually consists of a pair of lines ruled on a glass plate at known distance apart, and can be bought for a couple of dollars. This outlay, however, is unnecessary if the following method is employed.

Take a good watch and measure the exact radius of the hour hand, that is, from the tip to the center of the pivot. Suppose this is found to be 0.57 inch. Then the path of the point in 12 hours will be $2 \times \pi \times 0.57 =$ 3.58 inches. Therefore, it will move 1/100 inch every 2 minutes and 1 second. If the crystal is opened and the microscope focused on the tip of the hour hand, in 2 minutes and 1 second it will have moved 1/100 inch, and will fill the same purpose as the lines ruled on the glass. To the side of the barrel of the microscope fasten a piece of sheet metal with a small hole in one end and bent as shown. The distance between the hole and center of the eye-piece must be the same as the distance between the experimenter's eyes. On the table below the hole fasten a ruler running across the table, i. e., forward and back from the operator and exactly 10 inches from the hole. This 10 inches is the arbitrary distance selected in this country for such measurements. The watch must be so placed that the hour hand is moving directly toward or directly away from the operator. Now, upon looking in the microscope with one eye and through the hole with the other, the watch hand and the ruler will appear to be one on top of the other. Note the exact point on the ruler where the hand is at any instant. Then let 2 minutes and 1 second pass and again note the position. If the distance moved is 2.5 inches it will mean a magnification of $\frac{2.5 \text{ inches}}{0.01 \text{ inch}} = 250$ diameters. A little practice will enable a person to hit the time very closely. This can be repeated for various conditions, for low power lenses a greater distance than 0.01 inch being taken and for higher powers perhaps a shorter one.

The next thing is to construct a scale for the measurement of microscopic objects. The scale reads in thousandths of an inch, but each thousandth inch is magnified according to the power of the microscope. Thus, where the magnification is 250 diameters the "thousandths" will be ¼ inch apart. The proper length and divisions for the scale (or scales in the case of several objectives) can be figured and can then be drawn on a strip of cardboard. To measure an object it is only necessary to put the scale in the same position as the ruler in the first experiment. The object will then appear right on top of the scale and can be measured as easily as a carpenter measures a board. *Caution*. Always hold the scale at right angles to the nearest edge of the table. If it is laid parallel to a line connecting the hole and the eye-piece it will be nearly impossible to make a measurement. This is easily proved by trial. Also remember that the scale must be 10 inches from the hole. If this is an inconvenient distance owing to the shortness of the microscope any other distance can be adopted, as 8 inches, but in this case each division must be 8/10 as long as for the regulation distance.



Device for measuring the power of a microscope.

How to Remove Black Paper Strips from a Film Back

By Stanley P. McMinn

IN removing the black paper strips from a film pack such as commonly is used by countless numbers of amateur photographers, trouble not infrequently is experienced by reason of the paper tearing off before it has been completely withdrawn. Under ordinary circumstances, in order to nullify the effect of the remaining piece of black paper, it is necessary to pull out the next flap, thereby sacrificing one exposure. It is quite possible, however, to remove the section of black paper without destroying the exposure or disturbing the film remaining in the pack, with the aid of the gummed portion from an envelope. The envelope flap first should be trimmed to the width of the film pack, an envelope made of fairly heavy paper would better be used, though almost any thickness will serve the purpose. Then if the gum is moistened, which by reason of the slippery nature of the mucilage will operate to lubricate it, little difficulty will be experienced in slipping the improvised "fish" down between the torn-off paper and the next black strip in the pack. Care should be taken, of course, to ascertain that the gummed portion of the envelope comes in contact with the torn paper and not with the next black strip. The envelope should be permitted to remain in position for about 10 minutes, or until the gum has had time to harden thoroughly, when it will be a simple matter to draw out the torn strip by grasping the free end of the envelope.

An Interesting Static Electric Motor

By H. B. Dailey

FOR exhibiting in an entertaining way the effects of static electric attraction and repulsion, and for stimulating an interest in the observation and study of these phenomena there is perhaps no form of demonstration apparatus more effective than a static electric motor. While examples of static motors have occasionally appeared, the degree of mechanical skill involved in their making has usually been such as to discourage attempts at amateur construction. The features of extreme simplicity possessed by the efficient little motor here described should therefore commend it to the home experimenter.

The "tumbler" static electric motor

The apparatus employs three large equal sized tumblers of thin blown glass. The central tumbler, inverted, revolves upon a pivot pointed stem of 3/16 inch steel wire whose upper end enters a small indentation drilled in the exact center of the tumbler's bottom. A lower bearing is provided by fitting into the mouth of the tumbler a centrally apertured disk of stiff mica through which the supporting rod passes, the disk being secured in place with a little shellac applied to its edge. To keep the pivot stem from wearing the mica, a copper cent drilled to an easy running fit for the rod is attached to the mica disk with sealing wax. The tumbler, which is raised about an inch above the base, has cemented with shellac upon its outer surface eight equally spaced vertical strips of tinfoil 5/16 of an inch wide, with rounded ends, and of a length about 3/4 of an inch shorter than the length of the tumbler.

Upon opposite sides of the inverted tumbler and quite close to it are placed two similar tumblers, right side up, their bottoms fixed with shellac into snugly fitting recesses bored in the wooden base of the instrument. Each of the fixed tumblers has cemented upon its inside surface exactly facing the central tumbler a vertical strip of tinfoil ⅝ of an inch wide, rising from the bottom of the glass up to within ⅝ of an inch of the upper rim, the lower ends of these tinfoil strips, or field strips as they may be termed, being electrically connected with vertical knob-tipped metallic rods fixed in the centers of the outer glasses with a setting of plaster of Paris.

Lastly, from one of the upper corners of each of the field strips (from corners diagonally opposed on the field, strips face each other in the apparatus) a narrow tinfoil extension ⅛ of an inch wide rises vertically to the rim of the glass over which it passes, and terminates ⅜ of an inch down the outside of the tumbler. On connecting the two balls at the tops of the vertical rods with the opposite poles of a static machine, the central tumbler immediately begins a rapid rotation which continues to increase until the apparatus fairly hums.

In starting, the foil sectors on the central tumbler are at first attracted by the charged field strips within the outer glasses. As the sectors move into position opposite the field strips they receive sparks from the latter and become similarly charged, when repulsion ensues. Moving forward with the rotation of the tumbler they soon come within the influence of the oppositely electrified field strip on the other side and are strongly attracted, until as they pass the field strips, their electrification is reversed and the cycle is repeated. The moving sectors receive their sparks from the tips of the field strip extensions whose lateral displacement prevents the electrification of the sectors until the latter have come opposite the exact center of the field strips. The "tumbler" motor is a fascinating little machine to watch in operation, and when one sees its vigorous rapid action it seems incredible that the motive power is static electricity. The instrument operates satisfactorily from a very small static machine.

To Fill a Barometer Tube

By Henry H. Riggs

AMATEURS who have to fill or refill their own barometers are sometimes greatly troubled by the residuum of air which will remain in the tube in spite of all precautions, and spoil the vacuum and the accuracy of the barometer.

The following will be found a very helpful trick, though it will not take the place of other precautions for keeping mercury and tube clean.

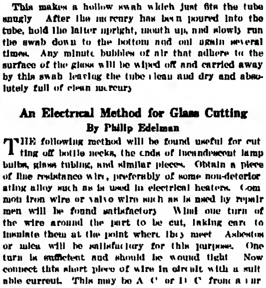
Take a piece of soft iron stove wire, and wind half a dozen turns around a large nail or rod of such a size that the coil will just slip inside the barometer tube. The coil must be a close one, with no spaces between the turns. Straighten the rest of the wire out so that it lies parallel to the axis of the coil. Finally wind a piece of cotton yarn in the coil so that it lies snugly in the groove between the turns of wire, bring one end through the coil and tie.

This makes a hollow swab which just fits the tube snugly. After the mercury has been poured into the tube, hold the latter upright, mouth up, and slowly run the swab down to the bottom and out again several times. Any minute bubbles of air that adhere to the surface of the glass will be wiped off and carried away by this swab leaving the tube clean and dry and absolutely full of clean mercury.

An Electrical Method for Glass Cutting

By Philip Edelman

THE following method will be found useful for cutting off bottle necks, the ends of incandescent lamp bulbs, glass tubing, and similar pieces. Obtain a piece of fine resistance wire, preferably of some non-deteriorating alloy such as is used in electrical heaters. Common iron wire or valve wire such as is used by repair men will be found satisfactory. Wind one turn of the wire around the part to be cut, taking care to insulate them at the point where they meet. Asbestos or mica will be satisfactory for this purpose. One turn is sufficient and should be wound tight. Now connect this short piece of wire in circuit with a suitable current. This may be A. C. or D. C. from a current tap or from a battery. If a current tap is used a resistance should be connected in series so as to avoid a direct short circuit on the line. If a battery is used it must have sufficient voltage and amperage to heat the wire. Allow the wire to come nearly to a white heat for a short time and then plunge the glass piece into some cold water. Holding the piece under a water tap will also do. The piece should then break cleanly at the point covered by the wire. The same general method can doubtless be applied to a variety of uses. There seems to be a limit to the size of a piece which can be cut in this manner, however. The worker can soon find the limits and then use the method to the best advantage.



Cutting glass with electric heat

The hot wire heats the glass in a restricted place which can be regulated by the worker as desired, and the heat does not spread all over the glass so as to cause an irregular break. The glass coming into contact with the cold water is subjected to considerable strain at the heated portion and consequently either breaks or cracks.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Pertaining to Apparel

SAFETY ATTACHMENT.—W P Aldan 25 Burnside St. Portland, Ore. This is an inexpensive device adapted for safeguarding a watch by attaching it to the clothing wherein a support is provided for the watch which will permit the watch to be taken from the pocket for inspection and returned without releasing the watch from the fastener or the fastener from the clothing

GARMENT SLEEVE.—A Goldberg 184 W 20th St Manhattan New York N Y. The invention refers to sleeves of garments such as shirts shirtwaists and the like and has reference more particularly to a garment sleeve having a cuff portion adapted to be held in different positions, and a part normally concealed by the cuff portion and constituting means for holding the cuff portion in a raised position

Of Interest to Farmers.

SEED PLANTER.—C Knopp care of H A. Turner R. F D No 1 Winnoe Minn. An object of this invention is to provide an implement which will be so efficient in action as to drop the seeds in sufficient number and at such distances apart as to avoid the waste of seed and labor in subsequently chopping out the superfluous plants.

DEVICE TO PREVENT DOGS FROM WORRYING SHEEP.—W Graham Cookshire, Quebec Canada. The object here is to provide a device which may be fastened to the nose of a dog and which is provided with hooks which will become entangled in the wool of a sheep so that when the sheep starts to run the dog's nose will be pulled, and the latter receive a lesson which will break him of his sheep worrying habit

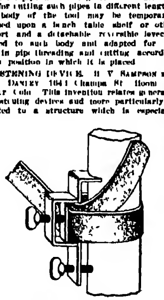
Of General Interest.

HORSESHOE CALK.—W Gordon 1743 N 8th St Philadelphia Pa. The object here is to provide a construction which will be easily applied to and removed from the horse's hoof at will, when in place be securely held against displacement in any direction and will embody means which will aid in the adjustment of the attachment to hoofs of different sizes

Hardware and Tools.

COMBINED PIPE VISE AND PIPE CUTTER.—C Brock 1721 Harford Ave Baltimore Md. This tool is for clamping and holding metal pipe while being screw threaded and also for cutting such pipes in different lengths. The body of the tool may be temporarily clamped upon a bench table shelf or other support and a detachable reversible lever is pivoted to such body and adapted for use both in pipe threading and cutting according to the position in which it is placed

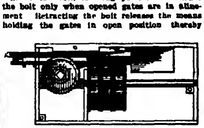
FASTENING DEVICE.—H V Sampson and S T Daniey 1041 Champa St Room 17 Denver Colo. This invention relates generally to fastening devices and more particularly is directed to a structure which is especially



FASTENING DEVICE.

adapted for securing the lines from the bridle bit or halter of a horse in order that the animal may be hitched to a post or other support. It provides a device especially adapted for this use which may co-operate with any hitching post or pole it being adapted to efficiently perform its purpose and at the same time being inexpensive in its make-up. It may be easily carried on the person and adapted for use with any hitching post in order to secure the reins or lines extending from the bridle bit or halter in order that the animal may be hitched. A perspective view of the device in operative position is shown in the engraving.

COMBINATION MASKET LOCK.—N S G Hagarity 808 Sussex St Paterson N J. In this simplified form of lock the combination to permit the actuation of the bolt may readily be changed from the outside of the lock. In this invention it is possible to draw the bolt only when the tumblers are in the position in which they were set when the bolt was thrown. A number of wheel-shaped tumblers are provided, having gates in their peripheries, which gates are adapted to be opened to permit the throwing of the bolt, which gates are locked in their open position after the passage of the bolt, it being possible to retract the bolt only when opened gates are in alinement. Retracting the bolt releases the means holding the gates in open position thereby

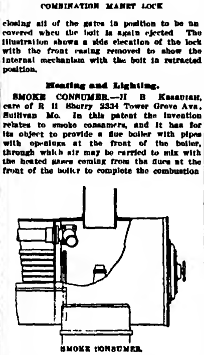


COMBINATION MASKET LOCK

closing all of the gates in position to be uncovered when the bolt is again ejected. The illustration shows a side elevation of the lock with the front casing removed to show the internal mechanism with the bolt in retracted position.

Heating and Lighting.

SMOKE CONSUMER.—H B Kasabian, care of R H Sherry 2334 Tower Grove Ave., Sullivan Mo. In this patent the invention relates to smoke consumers, and it has for its object to provide a flue boiler with pipes with openings at the front of the boiler, through which air may be carried to mix with the heated gases coming from the flues at the front of the boiler to complete the combustion



SMOKE CONSUMER.

Various applications of the invention may be used since the invention includes all constructions in which air is admitted between the fire chamber and the smoke stack whether flue boilers are used and whether the boilers are stationary or of other types. The engraving represents a sectional view showing the front of the boiler supplied with the smoke consumer

Household Utilities.

TRANSOM LIFT.—O W McCarty and D. F Harness care of D F Harness & Son Oklahoma Okla. The invention is an improvement in transom lifts, and the aim is to provide a simple inexpensive easily installed device by means of which the transom may be swung into any desirable position and so held and having automatically acting means for preventing accidental movement of the transom

BURNER.—J D Langston, 2502 5th Ave., Birmingham Ala. This burner is for use in cook stoves, ranges or heaters, adapted to utilise oil for fuel. The device is provided with means for gasifying the oil and burning the gas which may be applied to existing stoves, ranges or heaters, with slight changes to the stoves, ranges or heaters.

JAR COVER STRAIGHTENER.—R. S Knutson Steward Ill. In the present patent the invention has reference to household devices, and particularly to means whereby common metal fruit jar tops may be straightened after being distorted, and used repeatedly instead of discarding them unnecessarily

Machines and Mechanical Devices.

HYDRAULIC JACK.—F Lent 283 W 54th St New York N Y. The invention provides a jack for use on heavy trucks and the like and arranged to permit of conveniently raising the part without requiring much physical exertion on the part of the operator, to allow quick lowering, and to retain the liquid for re-use without danger of leakage

METAL ROLLING MACHINE.—J K Hauberg, care of J S Moothard, Cando N D. The distinguishing feature here is a roller carried by a reciprocating frame and adapted to act on a heated metal plate while held on an anvil block, and mechanism for adjusting such block higher or lower, or at different angles, according to the bevel it is desired to impart to the plate

YARN CONDENSER AND POLISHER FOR CORDAGE SPINNING MACHINES.—O Nenvidek R F D No 2, Milwaukee, Ore. This invention is an improvement in so-called nippers or machines designed for treating, that is to say condensing and rounding and polishing hemp, yarn or slivers preliminary to spinning for making ropes and cordage

PULLEY BRAKE FOR MOTOR CONTROLLED APPARATUS.—M. Tainman 241 Wooster St., New York, N Y. This inventor provides a readily actuated brake mechanism for simultaneously manipulating the brake to apply the same when the power is shut off, said mechanism having means for adjusting the support of the brake whereby the wear in the latter may be taken up and the effectiveness of the brake action varied.

Prime Movers and Their Accessories.

ROTARY ENGINE.—C. B. Eann, care of A. B. May 106 Wilder Bldg., Rochester, N. Y. This invention provides a simple form of connecting mechanism between the pistons whereby the intermittent and step-by-step partial rotary movements thereof shall be automatically controlled and whereby the intermittent rotations of the pistons through the inter-connecting controlling mechanism will result in imparting to a driven shaft a continuous rotary movement

STEAM HYDRAULIC INTENSIFIER.—T E Holmes, 8 Oakdale road, Nether Edge, Sheffield, England. This invention provides valve-controlled connections whereby the steam may, on the completion of its primary function be admitted to and allowed to act expansively in the steam cylinder of the intensifier so as to correspondingly reduce the quantity of steam required in this cylinder

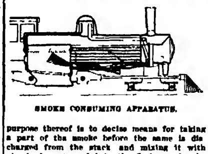
PACKING.—G E Walsot deceased, care of W A Kruger, 16 Newberry St. Providence, R. I. Use is here made of a tubular packing made in sections and encircling the rod or stem, the sections being provided with conical ends, the rings having conical openings engaging the said conical ends for holding the sections together and pressing the same against the rod or stem

Railways and Their Accessories.

APPLIANCE FOR CONTROLLING MOVING TRAINS.—J F Kimaas, Apple Creek Ohio. By means of this device a letter telegram, or order may be held in position to be caught by a trainman on a moving train wherein the inclosure may be so held that there will be no possibility of failure on the part of the trainman to locate the inclosure by day or by night and will release the inclosure as soon as traction is made thereon

METALLIC RAILWAY TIE AND RAIL FASTENING THEREFOR.—M J Shannon, care of A G Kerns, Wallace Idaho. This invention is an improvement in metallic ties and devices adapted to support rails thereon and to secure the supports and rails themselves thereto. Means provide for the introduction of a wedge to raise a block becoming lowered by wear, also to compensate for compression and wear of the cushion plate. The latter may be made of paper and will deaden sound and prolong the life of the rails

SMOKE CONSUMING APPARATUS.—H N Martin Chichester and Morris Aves. Morris Park L. I N Y. This apparatus is designed to be applied preferably to locomotives and traction engines in general, and the



SMOKE CONSUMING APPARATUS.

purpose thereof is to devise means for taking a part of the smoke before the same is discharged from the stack and mixing it with air, to be returned into the firebox, whereby all the particles of carbon and other inflammable substances suspended in the smoke and other gases, can be completely consumed before the smoke is discharged through the stack into the surrounding atmosphere. In the engraving a longitudinal sectional view of a locomotive is shown to which the smoke consuming apparatus is applied

RAIL.—H Collins 69 East 87th St. Manhattan New York, N. Y. The invention relates more particularly to rails such as are used in streets and flanked by the pavement with

RAILROAD RAIL.

only the heads visible. The invention provides a rail arranged to permit convenient removal of a worn out rail head and replacing the same by a new one without disturbing the position of the remainder of the rail on the ties and without requiring tearing up all of the pavement flanking the rail, thus saving considerable expense on rails and time and labor in replacing worn out heads by new ones. For this purpose use is made of a rail head seat, a removable rail head seated on said seat, and wedges for wedging the rail head in place on the seat. The engraving shows a transverse section of the rail.

BLOCK SIGNAL SYSTEM.—W A Lacer, 8010 Constance Ave., Chicago, Ill. By the use of this electrically-operated mechanism a semaphore arm, or analogous member, may be caused to assume a number of separate positions under the automatic control of the rolling stock, and after the signalling members is once set in any of its positions by aid of an electric current, no further current is used in holding it in such positions.

RAILROAD TIE AND RAIL FASTENER.—F C Shaman, 8 Academy Place, Oneonta, N Y. The intention here is to provide certain new and useful improvements in railroad ties and rail fasteners whereby the ties are rendered practically indestructible and the rails are securely held in place to prevent the same from spreading.

EXTENSION DEVICE FOR CAR PLATFORMS.—K L. Elsner, 882 Union St., Brooklyn, N Y. The object in this case is to attach to the ends of the car adjacent the doorway a device which can be connected to move in unison with the door to bridge the space between the car and the platform as soon as the door is opened and thus eliminate all risk of accident and injury

Pertaining to Vehicles.

HEADLIGHT.—E L. Wicarty, care of L. D Kirkpatrick, 7 and 8 Mercer Bldg Aledo, Ill. In this case it is sought to provide the light on the frame of the car in such manner as to permit the adjustment of the light to cast its rays either straight forward or at any desired angle either to the right or to the left, whether the car is moving or still.

TIRE INFLATER.—W A Vinson R. 5 No. 44 Vancouver Wash. An object of this inventor is to provide a simple and efficient tire inflater adapted to be operated by the motor of an automobile or the like and serving automatically to maintain the pneumatic tires of the vehicle inflated at a predetermined pressure

MOTOR VEHICLE DRIVING GEAR.—J A Schaaf, Richwood, Ohio. This invention provides a mechanism employing a plurality of driving friction disks and plurality of movable transmission wheels operatively engaged therewith, means for shifting the wheels to engage and disengage the disks in planes perpendicular to the disks whereby extreme width of the friction surface of the wheels is made effective, provides mechanism for shifting the disks by varying the speed of transmission and for discontinuing the same and provides for varying the speed of transmission mechanism on opposite sides of the vehicle to produce an effect similar to that obtained when employing a differential mechanism while following a curved path.

SANDING DEVICE FOR AUTOMOBILES.—L W Samuels, 585 W 113th St Manhattan, New York N Y. In this device for automobiles and similar vehicles a hollow mud guard is utilized as a sand receptacle and is provided with means for controlling the discharge of sand upon the periphery of the wheels for the purpose of preventing skidding

Designs.

DESIGN FOR A PENHOLDER OR SIMILAR ARTICLE.—M Bernstein 3607 Broadway New York N Y. In this design for a pen holder, the handle is gourd shaped in beautiful lines and ornamentally scrolled at the larger end. A chain hangs from the article, and at the small end of the latter a pen is inserted.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee title of the invention, and date of this paper

INQUIRY COLUMN

Inquiry No. 9286. Wanted household novelties or business necessities which can be retailed at from $1 to $3.

Inquiry No. 9287 Wanted to buy a machine which will reduce cobs to meal—not a machine for shredding the cobs, but a machine that will pulverize them.

Inquiry No. 9288 Wanted the names and addresses of concerns that can coat steel balls with pure tin one-sixteenth of an inch thick.

Inquiry No. 9289 Wanted substance melting at 212° and hardening when cold without imparting any flavor to tobacco smoke and without emitting any oily or fatty vapor

Inquiry No. 9290. Wanted name and address of a manufacturer of a patented device which is suitable for making up pay envelopes, namely, to fold up bills and insert them with other coins in a pay envelope of the usual size.

Inquiry No. 9291. Want to buy machinery for manufacturing wooden tooth picks.

Inquiry No. 9292. Wanted a gum that will stick labels to grape-fruit.

Inquiry No. 9293. Wanted the names and addresses of manufacturers of waterproof cloth [illegible]

Inquiry No. 9294. Wanted to buy [illegible]

A Parcels Post Tunnel Railway

(Concluded from page 5.)

gears to an electric motor mounted on the front end of the car At the rear end there is a small trolley pole with a T shaped head, which bears upward against the under side of the conductor rail. A reversing switch for changing the direction of motion of the car is located close to the trolley A direct current of 230 volts is used in the propulsion of the car, the current going out through the conductor rail and returning by the central track rail. In order to isolate the electric circuit and to give a direct current of desired voltage the power is supplied by a motor generator The small car can be driven at almost any reasonable speed, since there is no tendency to leave the track in turning sharp curves, but it is believed that in service a speed of 20 miles per hour will be found most practicable. If an ordinary two-rail track were employed instead of the three-rail construction described, it would be impossible to give sufficient super-elevation of the outer rail on the curves of so short a radius to keep the car on the track at maximum speed, but with the three rails the outward thrust due to centrifugal force is taken by the outer guide rail, and there is no component tending to derail the car Cars can be dispatched singly or coupled in trains.

In the station the conductor rail is placed at the side of the track, and is connected to the generator through a resistance which gives the car a low velocity To move the car in the station the operator pulls a hand lever that throws a contactor out against this side rail, but on releasing the lever the contactor is drawn away from the rail by a spring, so that the car continues its movement only so long as the operator holds the contactor on the rail This makes it possible to easily move the car about in the station. The car is dispatched by running it into the tunnel far enough for the trolley to make contact with the overhead conductor rail, then it is propelled automatically along the line until it arrives at the station, where the trolley leaves the conductor rail, cutting off the supply of current to the motor The car is brought to rest by sliding on wooden skids which are laid on each side of the center rail Underneath the car are two wooden faced shoes, which are made to bear upon the skids by a slight depression in the center rail. This is similar to the method employed in stopping the cars of "roller coasters" seen at amusement parks, but differs somewhat in detail The car slides along the skids for a distance of 30 or 40 feet, coming gradually to rest without shock As soon as it stops, by lifting a handle the shoes are unlocked and allowed to swing upward, which permits the car to rest on the track again, and then it can be moved forward out of the way of the following car Cars can be run at intervals of half a minute, and they are prevented from overtaking one another by the use of constant speed motors. As the speed of each car is practically the same throughout its travel, regardless of curves or grades, a nearly constant distance is maintained between them. Experiments show that in descending the 5 per cent grade which leads into the station at the demonstration plant, the motor on the car becomes a generator and returns power to the line. This has the effect of a brake on the car and prevents excessive speed on down grades. In ascending the 5 per cent grade, no appreciable diminution in speed is noticed.

Where several stations are located along a line, automatic switching devices can be provided whereby cars can be made to stop at any predetermined station Such switching devices are not shown at the demonstration plant.

A series of careful experiments have been conducted to obtain data useful in designing future installations. A chronograph has been used to determine accurately the speed of the car at each point as it travels around the circuit. Contactors that close an electric circuit through the chronograph when the wheels

of the car pass over them are located at intervals of 20 feet along the track, thus recording the time of passage of the car over each 20-foot section of track. Half second intervals are also recorded on the chronograph by connection through the pendulum of a clock The power consumed by the motor on the car is registered by a recording wattmeter, the chart of which makes one revolution while the car makes the circuit of the track. An electrically controlled pen in the time circuit of the chronograph records half second intervals on the edge of the chart. Thus the records of the chronograph and the wattmeter are co-ordinated. Air resistances in the tunnel are measured by a photographic recording water column.

Progress of the Weather Bureau

THE annual report of the Chief of the Weather Bureau, just published, covering the fiscal year ended June 30th, 1912, while containing nothing of sensational interest, is a record of substantial progress in the meteorological work of the Government The following items are especially worthy of notice

As usual, the work of the Mount Weather Observatory heads the report The scope of this institution has been somewhat enlarged, as it now serves as a school of instruction for newly appointed observers, who spend a few months here before being assigned to stations in the field. For five years past the observatory has been making daily observations of the upper air with kites and captive balloons, in all kinds of weather The results of these observations, telegraphed to Washington, are sometimes highly useful to the forecaster at other times less so, hence the plan of making daily flights has been discontinued, and hereafter flights will be made only when there is a type of weather above the station that it is desired to explore. During the year three series of continuous kite flights were made for periods of 24 hours each, in order to obtain information concerning the diurnal variation of temperature at various altitudes in the free air The Bureau has published a valuable digest of all the sounding balloon observations heretofore made in this country, viz., 70 made by the Mount Weather staff at certain places in the West, and 59 made by the staff of the Blue Hill Observatory Studies on the relation between the temperature on mountain tops and that of adjacent valleys have been continued. These have a practical bearing on the question of air drainage and its effects on fruit in the valleys.

Perhaps the greatest desideratum in meteorology is more knowledge concerning radiation from sun, sky and earth, and the Weather Bureau is doing its part toward supplying this need The radiation received from sun and sky upon a horizontal surface is measured at Mount Weather by means of a horizontally exposed Callendar pyrheliometer Direct solar radiation is measured with the pyrheliometers of Marvin, Angström, Callendar and Abbot, and polarization of sky light is observed with the Pickering polarimeter and the Savart polariscope. The observations of polarization are employed in the study of atmospheric transmissibility, which not only varies with the weather from day to day, but also from year to year on account of causes not yet understood. All this is in line with the world wide efforts that are being made to find out how much energy we receive from the sun, how the amount varies, and how this energy is disposed of by the atmosphere and terrestrial objects. On the answer to these questions depends the explanation of the principal mechanical phenomena of the atmosphere.

The Weather Bureau is co-operating with the University of Pittsburgh in the study of the smoke problem, which of course has meteorological bearings. Several contributions to pure science have been made during the year by the physicist of the Bureau, Prof. W J Humphreys, the most noteworthy being his explanation of the double diurnal fluctuation of the barometer.

The dream of the weather forecaster is to have at his disposal daily synchronous charts of the meteorological conditions over the whole world. Year by year the realization of this ideal is being approached. The chart of the northern hemisphere drawn every morning in Washington has recently been made more complete by the addition of reports from Dutch Harbor, in the Aleutian Islands, Nemuro, Japan, Shanghai, China, and several stations in Asiatic Russia. Now the great question is to bring the oceanic areas into the field by means of wireless reports from vessels, and the most important step in this direction has been achieved through the efforts of the Chief of the Weather Bureau, who as a delegate to the London Radiotelegraphic Conference last summer induced that body to agree to a regulation giving weather reports priority over all other wireless messages except distress calls. The Weather Bureau has already framed a tentative plan for a weather service covering the North Atlantic Ocean, and this will doubtless be put into effect as soon as European co-operation can be secured. In waters adjacent to the United States an effective wireless weather service is already in operation

Other projects under way include an investigation of the mysterious "thermal belts" or "frostless zones" of the Blue Ridge Mountains, experiments with devices for frost protection, especially various coverings, which it is thought may be used not only for fruit trees, but also for vegetables and alfalfa, and, last but not least, a thorough experimental investigation of the errors of anemometers at high wind velocities.

The Respiration Calorimeter

ONE of the most efficient mechanical aids to the investigator of the changes which take place when a chemical substance or a plant or an animal is observed under controlled conditions is the respiration calorimeter of the Department of Agriculture

The first report of experiments with the respiration calorimeter was published in 1897, during the first year of Secretary Wilson's administration. Since that time numerous bulletins and other papers have appeared which have described the apparatus, noted very important modifications and reported the results of investigations. As time has progressed, the apparatus as originally devised has been greatly simplified and made easier of operation, and so developed that more factors can be determined than was the case at first.

The respiration calorimeter was designed and has been used for the study of problems concerned with the food and nutrition of man and animal, the value of different foods as sources of energy for muscular work, and other similar questions. It has recently been adapted to the study of fruit-ripening and other problems of vegetable physiology, and is equally useful for the study of a great variety of other problems, as for instance, questions of ventilation of houses and farm buildings.

The experiments with the respiration calorimeter have furnished new facts and figures of great importance to students regarding the processes of respiration and accurate information regarding the energy which man needs to run his body machine and the effects upon his energy requirements of sleeping and waking, rest and work, and other factors. It is now possible to discuss such questions on the basis of accurate measurements, and this was not hitherto the case. The question of the energy which man expends to digest and assimilate his food has also been studied.

A deduction of great theoretical interest obtained with the respiration calorimeter experiments is that the law of conservation of energy holds in the animal body. Such a conclusion is at the basis of many important deductions regarding rations and diets and the use which man makes of his food and farm animals make of feeding stuffs.

The human body is a complex machine,

It is important to know its efficiency as compared with other machines. Experiments with the respiration calorimeter show this to be 20 per cent that is, 5 units of energy must be supplied by the food to provide one unit of work. In this respect man compares favorably with the best steam engine, their efficiency, it is safe to say, not exceeding 14 per cent.

Whether or not physical energy must be expended for mental work as well as for muscular work is a question of interest. Judged by the results of a long series of experiments with the respiration calorimeter, severe mental work does not make demands for physical energy, at least in amounts that were measurable even with so accurate an instrument.

It is natural that an apparatus of this character should be used in the study of technical questions which cannot be approached by simpler means, and in part the results referred to above are technical. However, the usefulness of the respiration calorimeter is not limited to such matters, and it has been of great value in studying questions of everyday interest pertaining to food and the use which man makes of it. It is, in a large measure due to this and related work that we are able to discuss such matters to-day with reasonable certainty.

The feeding standard is something which the farmer of to-day realizes is necessary for success, and a progressive farmer bases his practice on the feeding standards which experimenters have provided for him. If we are to make the right use of our available food supply dietary standards are needed, and those proposed by the Department of Agriculture have had wide use. The proof of the accuracy, with respect to energy, of these dietary standards, has been obtained from experiments with the respiration calorimeter.

The discovery that the respiration calorimeter is equally as valuable for studying ripening fruit processes and other problems of vegetable life and for the study of man's food and the way to use it, has opened up a new line of work. With the apparatus which has been built for this purpose and the larger respiration calorimeter for experiments with man, the Department is in a position to continue its investigations of technical and practical problems and to accumulate very useful and valuable information. The first stage in a valuable kind of work has long been passed, the apparatus and methods have been perfected, and facts of great value have been secured. New fields of usefulness are being entered upon, and the outlook for rapid accumulation of additional data of great importance to all who are interested in the profitable and proper use of agricultural products is assured.

How the Wind Carries Pebbles of Large Size

It has been proved that a wind having a velocity of 23 meters per second is capable of transporting through the air particles of sand only when they do not exceed 2 millimeters in diameter. Yet occasional "rains of stones" of much larger size are occasionally observed. Thus, there is a record of the fall of stones in the Canton de Vaud having diameters ranging as high as 1½ centimeters and of weights up to 2.62 grammes. The nearest region whence they could have come was Maures and Esterel. The case is known also in Château Landon of small calcareous stones of 3 centimeters diameter being carried 150 kilometers.

In Sweden in 1883 stones as large as filberts, enveloped in large ovoid hail stones and weighing nearly 6 grammes, were carried 60 kilometers.

M. Thoulet discusses such cases in *Les Annales de l'Institut Océanographique* and suggests a plausible explanation. He thinks we must accept the idea of some sort of fixation around the pebbles of an envelope of air or vapor of water. The density of the body transported would cease to be that of the pebble, and become that of a mass of combined solid and fluid (or gaseous) matter, which would be sensibly lighter with respect to its volume

NEW BOOKS, ETC.

CHEMICAL RESEARCH IN ITS BEARINGS ON NATIONAL WELFARE. London Society for Promoting Christian Knowledge, 1912. Price, 50 cents.

The major portion of this little book is the lecture delivered by Prof Fischer before the Kaiser Wilhelm Society It gives a very interesting glimpse of the achievements in chemical research which have made Germany one of the most important manufacturing nations in the world.

LUFTSCHRAUBEN Leitfaden fuer den Bau und die Behandlung von Propellern. Von Paul Bejeuhr Mit über 90 Textabbildungen. Frankfurt a. M Verlag von Franz Benjamin Auffarth 1912.

The author of this book assures us that it was written as a result of practical experience for practical men It presents no new theories, but on the other hand it discusses clearly and fully the prevalent views on propeller construction and action with the object of so familiarizing the reader with the subject that when a new theory does come forth, he will be able to judge it critically Starting with a few elementary principles, the author discusses the methods of such men as Wellner Ferber Eberhardt Lanchester etc He explains how propellers are tested by various machines. He leads the reader by the hand through a propeller factory and shows him how the best aeroplane and airship propellers of the day are constructed. The book concludes with a compilation of the most important formulæ.

BAU UND BETRIEB VON PRALL-LUFTSCHIFFEN Von Richard Basenach, Ingenieur in Berlin I Teil Frankfurt a. M Verlag von Franz Benjamin Auffarth, 1912.

It is the author s intention to discuss the subject of the dirigible airship in three parts. This is the first As might be expected it is devoted to a clear discussion of fundamental principles. The second and third parts we are promised will enter more in detail into the niceties of construction and operation In this first part, the author has presented an account of the underlying principles of the dirigible airship which must be read with lively interest not only by the layman but even by the professional builder of airships. It is not often that we find expert information delivered so lucidly and so instructively

ADDRESSES TO ENGINEERING STUDENTS. Kansas City, Missouri Waddell & Harrington, 1912 8vo, 563 pp Price, $1

Some time ago we made favorable mention of this collection of papers Within three months of the issue of the first edition of three thousand copies the supply was exhausted and a second edition made necessary Its present form includes five additional papers of special importance and as the work is not a money-making venture but a true effort to place before engineering students and practicing engineers a series of papers by the greatest authorities, that shall prove a help and an inspiration the success of the enterprise to date is encouraging and its continued appeal is a foregone conclusion.

EFFECTS OF ERRORS IN SURVEYING. By Henry Briggs, M Sc Philadelphia J B Lippincott Company, 1912. 12mo., 179 pp, illustrated

The theory of errors a branch of the theory of probabilities, owes its development to the labors of Gauss while Bessel, following him gave to the world valuable methods for distributing errors in triangulation and was also the first to apply these processes to trigonometrical surveys There are a number of good text-books in existence dealing with the application of the law of the least squares to triangulation but comparatively little progress has been made in investigation of the propagation of error in surveys Hence the work in hand is a welcome contribution to the study of errors and their combination as they may affect the accuracy of surveys. Rules are formulated against the occurrence of such errors and methods are devised whereby the mistake likely to occur in any given case may be properly accounted for, and taken care of The criterion known as the average error' has been adopted instead of that of the 'probable error In this the author is following sound precedent if not common usage, and he has at least easier computation on his side of the argument. Throughout, the treatment is frankly mathematical and the reader s familiarity with the elementary branches of the subject is taken for granted

THE GASOLINE AUTOMOBILE A Practical Discussion of the Development and Present Status of the Automobile. By Victor Lougheed and Morris A. Hall. Chicago American School of Correspondence, 1912. 8vo., 307 pp., illustrated Price, $2.

CARE AND OPERATION OF AUTOMOBILES. A Handbook on Driving, Road Troubles and Home Repairs. By Morris A. Hall. Chicago American School of Correspondence 1912 8vo., 140 pp., illustrated Price, $1

The two works are uniform in style and binding and constitute a helpful contribution, albeit in an already somewhat crowded field. Disclaiming "The Gasoline Automobile" as in any way exhaustive, the publishers have designed it to meet a need for a reliable, readable presentation of the elements of the gasoline motor and its accessories, with a discussion of the newer features of the modern car. Illustration has not been spared, and the aims of the publishers have been adequately carried out by the authors. In the 'Care and Operation of Automobiles," is presented as a separate volume the latter part of the first work In other words, there is practically nothing in the 'Care and Operation of Automobiles' that is not included in "The Gasoline Automobile. It simply allows those who want the practical suggestions on care and operation, and do not wish to study development and present status to get these suggestions in separate binding This should be distinctly understood The information concerning private garages and repairs is timely and gives some very good pictures showing exterior appearance and interior arrangement. A list of the necessary tool equipment and its cost is given, with many home-made devices and conveniences, and clear instruction in the use of tools and the carrying on of repairs at home. By following these suggestions and directions, much of the expense of public garage repairing may be avoided, and the owner acquires a knowledge of his car and of repairs methods in general that cannot fail to be of the highest service to him on the road.

THE MODERN LOCOMOTIVE. By C Edgar Allen. New York G P Putnam's Sons, 1912 16mo, 174 pp, illustrated. Price, 40 cents net.

As one of the Cambridge Manuals of Science and Literature, this little primer upholds the reputation of the series. Within its narrow confines is packed an astonishing amount of information regarding the design and working of the modern locomotive—the generation of its steam combustion and vaporization, superheating, and traction effort. Frames and running gear stability performances and speeds—all are popularly but efficiently discussed and glimpses are given into the wonderful methods and achievements of the locomotive shop.

RUBBER TRADE DIRECTORY OF THE WORLD, 1912 New York The India Rubber Publishing Company 8vo, 313 pp. Price, $3 50.

This directory is issued under geographical divisions covering the United States and Canada, Central America, South America, Europe, Asia Africa and Australia These major divisions each include minor divisions which classify rubber goods factories, rubber planting companies, rubber and waste dealers, manufacturers of compounding ingredients, of rubber machinery etc. In short the directory has been vastly enlarged in scope since its first appearance in 1908 In the plantation list, it cites only those companies that are on an established basis. Yet we find listed no less than 132 rubber plantations with offices in the United States and Canada. Many influences have been at work during the past few years tending to unify the various branches of the rubber industry and the factory end of the industry no longer lacks interest in the planting and cultivation of the product The directory will doubtless be put to extensive use by manufacturers, importers reclaimers waste dealers, and planting companies.

FIRE PREVENTION A Treatise and Textbook on Making Life and Property Safe Against Fire By Peter Joseph McKeon. New York The Chief Publishing Company, 1912 Price, $1 75

An expert has here dealt with the reduction of fire prevention to a science giving the reader a very full and complete set of instructions for the prevention and control of fires. He addresses himself to the owner and the occupant and urges their co-operation with the department by making the buildings safe against fire by removing dangerous material by an adequate equipment of water pails, chemical extinguishers, standpipes, and automatic extinguishers by automatic alarms and watchman service by special signal calling the firemen direct to the building by localizing the fire by means of brick-inclosed stairways and elevators by seeing that stairs, elevators, and escapes are readily accessible and by the establishment of the fire drill. The material is well arranged the various safeguards clearly illustrated, and the arguments sound The work may be recommended to business men, superintendents, janitors, householders, and the general public

MOULDING CONCRETE FLOWER POTS, BOXES, JARDINIERES, ETC By A A. Houghton, New York The Norman W Henley Publishing Company, 1912.

MOULDING CONCRETE FOUNTAINS AND LAWN ORNAMENTS. By A A. Houghton. New York The Norman W Henley Publishing Company, 1912

These two little volumes are respectively No. 10 and 11 of a series of concrete workers' reference books. Both give helpful, practical suggestions for manipulating cement for the purposes indicated by the titles of the books. Any man who is reasonably skillful with his hands ought to be able to follow the suggestions given in these volumes.

LES RAVAGEURS. Récits sur les insectes nuisibles à l'agriculture. Par J.-H. Fabre, correspondant de l'Institut. Un vol. in-18, illustré de 16 planches hors-texte en photogravure. Paris Librairie Ch. Delagrave, 1912.

M Fabre has made an international reputation for himself as a scientist who knows how to present the facts of entomology in a popular and readable way The denizens of the garden, the meadow and the field are here described with a literary charm that commands admiration. The book is written in dialogue form, which has the advantage of injecting the human element into the discussion.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12723) F C De M asks Can you advise process of staining or coloring sheet aluminium a dead black? A A formula for blackening aluminium is as follows White arsenic, 1 ounce sulphate of iron 1 ounce hydrochloric acid 12 ounces water 12 ounces. Dissolve the iron and arsenic in the acid and add the water Clean the aluminium thoroughly with fine emery powder and wash before immersing it in the blackening solution When the blackening is deep enough dry off with fine sawdust and lacquer

(12724) R C J asks Some time ago the SCIENTIFIC AMERICAN contained an account of how a high-votage line had broken and how the current passed across a plowed field fusing the soil into a hard mass. Why not use this idea in the construction of roads? How much current would you need to fuse the earth three inches deep? A We are not able to answer your question as to making a road by the fusion of the earth by an electric current The accidental fusion of a line across a field is a very different matter from the making of a roadbed wide and deep enough to serve for traffic. The cost even where electricity is very cheap would certainly be very heavy

(12725) D M writes According to the scientists investigations show that the Aurora is no doubt due to streams of electric corpuscles which are thrown off from the sun during sunspot activities and repelled by the repulsive force of light at immense velocities in all directions from that orb and that when the earth encounters such streams they are drawn toward the magnetic poles where they recompose or condense as it were, producing the beautiful auroral light.

The strange feature of the case is that in all the active displays which I have observed the motion of the light is always upward, for one will see a brilliant patch of light start at the bottom of the curtain or streamer and shoot upward with a tremendous speed giving one the idea that such electricity was being discharged away from the earth and not being received, for under such conditions the light would appear, I should think as falling toward the earth.

Again if such electrical energy was being drawn toward the earth why does not the Aurora touch the earth within the immediate vicinity of the magnetic poles? From recent observations the altitude of the Aurora varies from within a few miles to eighty or more while in some of the earlier works on the subject a curtain was observed to be only a few hundred feet above the ground while rays have been seen to apparently touch the ground in Arctic regions but perhaps this was the effect of mirage Weather Bureau kites and captive balloons have, I understand reached an altitude of ten miles Now do you not think they would be of some value in determining condition of temperature pressure humidity and electrical state of the atmosphere if sent up during an aurora? For as before stated such displays especially in the zone of maximum frequency which passes through Norway etc occur at no very great height If such calculations are correct a kite or balloon could be sent right into the heart of the Aurora's mysterious glow and much might be gained. I should like very much to know more about this interesting phenomena and what some of your readers might have to say A The occurrence of magnetic disturbances simultaneously with auroral displays and the fact that auroral streamers coincide as nearly as we can tell with lines of magnetic force are two good reasons but not the only ones, for believing that the auroras themselves are of electrical origin But it is not yet certain that this origin is the bombardment of the outer atmosphere by streams of solar electrons. Indeed recent calculations by Prof Schuster show that even if a stream of electrons should leave the sun their mutual repulsion would completely dissipate them before they possibly could reach the earth However as Schuster says, there conceivably may be solar streams of non-electrified particles that somehow or other excite auroral activity but this is mere speculation The electrical nature of auroras is fully conceded but what it is that excites them to activity is not definitely known Auroral streamers *appear* to shoot upward not because of the direction of the discharge, which, like lightning is far too fast to follow but because of growth and increased intensity With decrease of intensity they often appear to drop back but this too gives no indication of the direction of the electrical discharge. Just why there is an auroral ring around each terrestrial magnetic pole inside of which auroras are seldom seen, is not yet a settled question. It has been extensively discussed but not fully solved. As suggested kites and balloons might be sent up at the time of an auroral discharge, but there is no good reason to expect the gain in this way of much additional knowledge about auroras. Kites seldom reach an elevation greater than four miles, nor captive balloons more than two miles, while the region of the auroral discharge appears (nearly always) to be thirty miles and more. Sounding balloons have in rare instances, gone to an elevation of 18 miles. This is far short of the main auroral level.

Sixty-Ninth Year

SCIENTIFIC AMERICAN *for* 1913

AS WE go to press for the first issue of the 69th year of the Scientific American we should like to be able to publish an approximate table of its contents for 1913 Although this may be possible for some journals, with the Scientific American it is obviously out of the question As stated at the head of our editorial colums "The purpose of this journal is to record accurately, simply and interestingly the world s progress in scientific knowledge and industrial achievements " Scientific knowledge and industrial achievements are undergoing phenomenal developments, the progress of which will be chronicled in these pages But what these developments will be who can foretell? So, in forecasting the Scientific American of 1913 we can only refer back to the year just past as an index of the manner in which the subjects for the coming year will be treated, and as a measure of our own development, we invite comparison between the Scientific American for 1912 and that for 1911

Although a table of contents is now out of question, we are able to announce a series of subjects that will come in for special attention These will appear in special magazine numbers which will be continued this year, as they have been in the past two years The list of subjects is indicative of the broad scope of the paper, which concerns itself on the one hand with the vast powers of nature, and on the other with the minute micro-organisms of bacteriology, the great agricultural operations made possible with modern machinery

In the following list of magazine numbers it should be understood that the subjects given out will not monopolize the whole of the number, but each number will contain the same variety of subjects as do the regular issues of the Scientific American

Motor Number
JANUARY 11

NEXT week the Scientific American publishes its fifteenth annual motor number This unlike the other magazine numbers will be wholly devoted to the subject of the automobile and the motor truck Topics of special articles are Automobile Bodies, Past Present and Future Partnership Ownership of a Car Kerosene Engine Carbureters and Convertors How to Realize Economy with a Motor Wagon Left side Steering and Central Control and the Capabilities of the Motor Truck and the Horse Compared There will also be a valuable table classifying all American made cars according to price, showing what cars can be bought for $500 $1 000 $1 500 etc

Agriculture
FEBRUARY 1

FOLLOWING our practice of the last two years the February number will take up the subject of agriculture giving the latest information on improved agricultural machinery and the scientific treatment of soils

Water Supply
MARCH 1

THE tallest building in New York towers 750 feet above the ground—the deepest hole sinks as far below ground giving access to the Acqueduct Tunnel under the East River Although the acqueduct has been described from time to time in the Scientific American it is hard to give an adequate idea of the greatness of this engineering undertaking In our March issue a general survey of the whole aqueduct will be given

Harnessing Nature
APRIL 5

COAL will not last forever What shall we do when it is gone? Of the great powers of nature we have succeeded in harnessing so far only those of the wind and the flowing stream but there are open to us still the enormous power of the waves and the energy that the sun is constantly sending us in the form of light and heat Many efforts have been made to utilize wave power but so far with little success. Just what has been done will be fully explained in the April issue Also there will be an article on the utilization of sun power in which line some very promising experiments have been made

Safety in Travel
MAY 3

IT is time for radical improvements in the conduct of railroads It is time that the automatic stop for trains was adopted not to relieve the engineer of responsibility but to act as a check upon him and to come into operation only in case of a lapse on his part.

Bacteriology
JUNE 7

THIS issue is taken up with the greatness of the infinitely small It will explain how some micro-organisms are our enemies and others our friends and how we may make alliance with the latter to war upon the former

Compressed Air
JULY 5

NOT a steel building not a bridge not a tunnel of any description has been built in this city without the use of compressed air Why should this power be used in place of electricity? The advantages of compressed air and the peculiar conditions requiring its use will be explained in the July issue

Electric Furnace
AUGUST 2

IN this issue we shall deal with the electric furnace as used not in the manufacture of steel but in the laboratory where the intense heat it furnishes permits of chemical operations that enable us to reproduce artificially nature s own work in manufacturing diamonds, precious stones and other valuable products.

Waterways
SEPTEMBER 6

IN this number we are reminded that we must not be so engrossed in the Panama Canal as to forget the important waterways in our own immediate neighborhood The Cape Cod Canal the Canadian canals, harbor improvements the widening and deepening of our navigable streams etc

Paper—Its Use in the Arts
OCTOBER 4

THE subject which is to be taken up in this issue is full of great interest Not many realize to what extent paper and wood pulp enter into the arts, to suggest the various uses here would be to spoil the coming story

Great Inventions of Our Time
NOVEMBER 1

ALTHOUGH all important inventions are described in the Scientific American there are some that stand out above the rest and that are of an epoch-making character These will come in for particular attention in the November issue

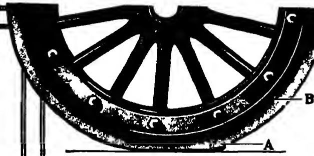
Panama-Pacific Exposition
DECEMBER 6

THE last magazine number of the year will be devoted to the Panama-Pacific Exposition and the opening of the Panama Canal to active service, which will mark a new commercial era for the United States.

The subjects referred to in the magazine numbers will be written by specialists in their several departments. Although we have made special detailed reference to these numbers it must not be inferred that all the interesting material will appear in them The regular weekly numbers will contain the same variety of matter that they have in the past and we shall by no means follow the policy of saving the best for the magazine numbers.

STUDY the illustrations! They show how you can double the efficiency and profit of your heavy service truck.

The upper cut shows the "traction" wave always formed in the ordinary continuous tire under heavy load. This wave, caused by the bulging of the rubber, works into the base and tears the tire from its fastenings. It can't be avoided in any ordinary way. Then, too, this wave forms a constant hill—the tire is always climbing, retarding progress, reducing power efficiency.



Showing traction wave in ordinary continuous tire (A) indicates where wave forms. (B) indicates base where roll and tread separation occur

Contrast this condition with the profit-making worth of—

Firestone

Continuous Base—Notched Tread

Truck Tires

The lower cut shows how the Firestone Notched Tread overcomes the wave, by preventing its formation This is *not* an individual block tire, with tread-tearing, metal-retaining plates The Firestone continuous base is of the same tough, resilient compound as the tread These tires hold the road, increase traction, absorb all vibration

Get the full facts. They mean Economy and Increased Profits

Firestone Truck Tires for Every Type of Car, Every Load, Every Road Condition

The Firestone Line of Truck Tires has in it the tire, solid or pneumatic, you need for your particular service Get the books which tell the story Ask, as well, for Quick Removable Rim facts They are valuable

The Firestone Tire & Rubber Co.

Showing how Firestone Notched Tires overcome destructive traction wave (A) indicates wave passing off into space between blocks. (B) indicates continuous base assuring absorption of vibration in every direction

America's Greatest Touring Cars are Premier Sixes The First of the Five Leading Makers to Establish the New Price Basis for the Six was the Premier

THE public has decided that the high-class car of the future must be a Six. The Premier is one of the four makers whose six-cylinder cars have created this six-cylinder demand. Seven years' production of successful sixes.

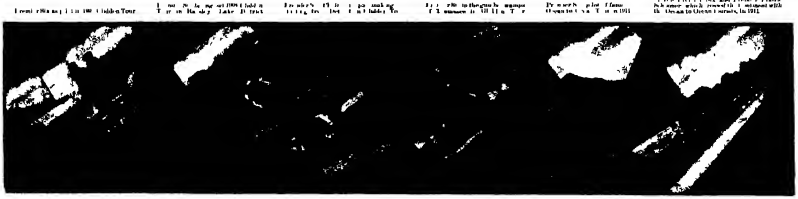
The Premier six-cylinder is not only a leader in price but in style and appointments. It is fitted with pneumatic starter, pneumatic tire inflator, independent electric lighting system, imported magneto, imported annular bearings, left hand drive, clean running boards, a cabinet mounted in the dash providing a tool carrying compartment, gasoline fed by gravity with filling cap accessible without removing the cushions, luxurious upholstering, Turkish cushions, concealed hinges, and straight line bodies finished with the pleasing touches which make for elegance and class.

Premier Sixes, $2735 to $4000

FULL TOURING CAR EQUIPMENT

The Premier has earned its position as one of the leaders among America's leading cars by its wonderful performance and successful showing in the most trying tours and contests each year.

Manufactured by PREMIER MOTOR MFG. CO., Indianapolis



Electricity's Part in the Automobile

Electric Lighting

F Mazda He

Without the application of electricity it is probable that the automobile as we know it today would not be so convenient and safe a means of pleasure, business and travel

The gasoline car is dependent on an electric spark the electric car upon its storage batteries

When lighting up time comes safety is in a large measure due to a dependable lighting system and satisfactory lamps

On all representative cars ***Edison*** Mazda automobile lamps have been adopted as standard Due to the large volume of light given by ***Edison*** Mazda Lamps for comparatively little current, electric generators and batteries were made small and light enough to be incorporated in the equipment of the modern, up to-date car

The General Electric Company was not only the pioneer in the development of automobile lamps, but is t day the largest manufacturer in the world of this type and of every other type of incandescent lamp

This company is in the closest co operation with car builders and makers of electric lighting systems—the result therefore is the most efficient lamp for all conditions of automobile service—the ***Edison*** Mazda This lamp has a strong sturdy filament made from drawn tungsten wire In connection with electric lighting a number of wiring devices are made which facilitate connecting and disconnecting lamps for permanent or portable use The switches which control the lights also bear that hallmark of quality of the largest electrical manufacturer in the world

Three Circuit Snap Switch

Electric Motors and Controllers

It is a real pleasure to step into a luxuriously fitted electric carriage and by the movement of a single lever apply and govern the propelling force Nothing takes the mind from the fullest enjoyment of the ride

Starting out in evening clothes, without a chauffeur, one can be sure of arriving at his destination with certainty and an unruffled temper if the car is equipped with a dependable power plant, furnished by the General Electric Company, such as has been adopted by electric car builders of the United States using more than 65% of all the electric vehicle motors built

Automobile Motor

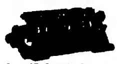
This power plant is so unobtrusive and demands such infrequent inspection or adjustment, that its presence in the vehicle may almost be forgotten

The motor of an electric car must be efficient and light in weight This is to give the greatest possible touring radius on a single battery charge and thus preserve the life of the storage battery, which is dependent upon the number of times it is discharged

Automobile motors made by the General Electric Company meet all these conditions and in addition absolutely prevent over discharge of the battery on steep grades

The electrical design of the motor assures the best operating characteristics as well as embodies many important novel features which have made G-E motors pre eminent in the world's haulage today

The weight of the motors is reduced by the use of aluminum wherever possible and great strength is obtained by making the frame and head of a single piece cylindrical steel casting, machined from end to end



Automobile Controller Continuous Torque Type

The controllers made by the General Electric Company are of the continuous torque type securing smooth acceleration and deceleration under all conditions In both mechanical and electrical design they use the same features which have made G E street car controllers the standard of the world today

Because of the above reasons more than 65% of the electric motor and controller equipment used by automobile manufacturers of the United States is of G-E manufacture

Many merchants who require absolutely dependable delivery service are using in the aggregate hundreds of electric trucks Records show that these trucks are in use more days each year than any other kind of delivery vehicles and that their upkeep is much less

These trucks climb the steepest hills in deep snow or plow through heavy mud with equal ease and certainty

Electric Charging Devices

When Electric Automobiles were first introduced one of the most serious inconveniences connected with their use was to get the batteries charged

This difficulty has been removed by the invention of the Mercury Arc Rectifier, an inexpensive, easily operated device for changing the alternating current of the ordinary lighting circuit to direct current suitable for charging storage batteries With a Rectifier installed in the private garage the car does not have to be sent to the public garage for charging and is always ready for use The General Electric Company makes a small rectifier known as the "Runabout type, which has just the right capacity for charging the batteries of electric pleasure cars

Operating a Runabout Type Mercury Arc Rectifier

When the current supply is from an electric railway circuit, a motor generator set is used in place of a rectifier, but where direct current lighting circuits are available, as in the downtown district of New York City charging rheostats are all that is necessary

In all cases the convenience and usefulness of an electric are greatly increased by reliable equipment for home charging

The foregoing shows the many advantages due to electricity in its application to the automobile

Wherever that silent power called electricity is used, there will be found skilled engineers, backed by the wide resources of the General Electric Company, perfecting the product—making the G E monogram stand for the "guarantee of excellence of goods electrical"

Grueling Tests for Artillery

By Our French Correspondent

THE Krupp establishment is making use of some very efficient endurance or breakdown tests upon artillery, both for keeping up a check upon the standard types of pieces and for testing new designs. One of the most novel methods is the use of a circular electric testing track upon which a car is run in order to draw the artillery pieces over the ground at slow or high speeds as may be required.

At the Essen artillery grounds, which lie near the main factories, there is laid out a circular railroad track with a special kind of electric car running upon it for making the tests upon the artillery. The track has 210 feet mean diameter, which gives it a total length of about 660 feet, being substantially laid on beton and using a single rail on the outer side and a double rail on the inner circle so as to keep the car from running off the track. The railroad track proper is usually reserved for the electric car, while the artillery is run on a circular way which lies on the inside and also on the outside of the main track, thus allowing two pieces to be drawn along at the same time. The artillery track is slightly banked. The railroad track has a 7 foot 6 inch gage, and if desired, the artillery can also be run in the space between the rails. In order to vary the tests the nature of the ground is made different upon various parts of the circular tracks. For instance, some 320 feet of the track, or about half the circle, is laid with a good stone paving, while the remainder represents country roads in more or less good condition. Upon these different stretches of road there can be placed obstacles of various kinds, such as timber lying across the road, ditches or holes and the like. The use of the electric car for drawing the artillery has an advantage from the great number of different running speeds which can be employed, representing what a team of horses would give at a trot or gallop, and much higher speeds can be used when desired.

On the upper floor of a cabin is an inspection room which serves for engineers or official committees when making certain tests upon the artillery, whence the track can be overlooked. Signals can be sent from the track into the cabin in order to give notice to the operators, and for this use there are placed six signal posts around the track so as to send electric bell signals to the cabin during the maneuvers for changing speed or stopping and the like. Across the car is a bar to which the tongue of the artillery piece can be attached so as to run it on the outer, middle or inner track. The car is started up and the piece is taken around at the different speeds which may be required for any given case, so that it will be seen that the electric track allows any such maneuvers to be made very quickly and avoids loss of time. As regards the obstacles which are put in the way of the artillery piece to give it a severe endurance test, one of our engravings shows a field howitzer taking over a heavy piece of round timber and at a high rate of speed. Seeing that the artillery piece springs up to a considerable height and then falls on the ground and that its total weight is 2.4 tons, an idea of the good quality of the axles and wheels will be obtained. Another illustration represents an ammunition wagon being drawn at a high rate by the car and passing over a steep ditch dug on the track at this point. It should be stated that the track is well lighted by arc and incandescent lamps. Up to the present time the tests, which cover a period of several years, amount to as much as 40,000 miles run upon the circular track.

Some very severe tests of another kind are obtained by the use of steam locomotives running on a special stretch of railroad track at the company's artillery grounds at Meppen. At each side of the track is laid out a proving way containing surfaces of varied character or special obstacles. Our engraving shows two artillery pieces attached to a cross bar, each running on a separate way. Here the road is made up of heavy broken stone. When the locomotive is run at high speed this gives a very severe test, and in some cases the artillery pieces jump bodily from the road to a considerable height. This is the case in our present figure, where the obstacles consist of railroad rails laid crosswise and spaced along the way.

Other endurance tests of artillery are made upon actual roads in the country using a team of horses, as one of our photographs shows. The field piece is here passing over a very high obstacle formed of three logs bound together, and it springs a conspicuous height off the road.

Electric motor dragging an ammunition caisson through a hole with steep sides

A test over prepared roadway composed of large stones and boulders.

Recoil siege cannon upon carriage drawn by horses clearing a wooden obstacle at the testing ground of Tangerhütte

Two field guns and their fore-carriages drawn by a steam locomotive over obstacles consisting of railway rails

Showing Visitors How Cars Are Made

SOME of the labor-saving devices which were described in a recent issue of the SCIENTIFIC AMERICAN will be shown to the visitors of the New York automobile show in Madison Square Garden. Several typical multiple production machines will be exhibited in operation turning out standard parts in the same manner as it is done in the large automobile factories. This part of the exhibition will probably draw larger crowds than the mere show of the cars, for every one likes to know how the thing is done.

Automobile Accidents in Paris

ACCIDENTS due to automobiles are becoming more frequent in Paris owing to the development of the taxiauto cabs and autobuses. The official figures for last July show a total of 170 accidents during the month, of which the taxicabs are responsible for 59 accidents with 2 deaths. For the autobuses there are 11 accidents with but 1 death. The tramways figure for 20 (6 deaths), and private automobiles make up the remainder. It will thus appear that the autobus is not responsible for as many accidents as might be thought, and the complaints made by the public appear to be unfounded.

The Automobile in Egypt

THE use of automobiles is becoming quite extensive in Egypt within a recent date, especially at Alexandria and Cairo. The latest figures show as many as 563 cars registered at Cairo alone. Even though all of these are not in circulation, it is estimated that at least 400 are in regular use, and these are running almost entirely within the city. Outside of town there are but few roads, such as the Pyramids, Heliopolis and Kubbeh-el-Farag routes. At Alexandria there are counted 167 automobiles. The only good road outside the city is the 8-mile route leading to the resort of San Stefano.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement.

A Century's Decline in American Shipping

THE thirteen original States either bordered on or had easy access to the sea, and the First Congress, recognizing the importance and promise of our maritime interests allowed a rebate of ten per cent of the duty on all goods brought into this country in American vessels. That was in 1789. Under the stimulus of this wise provision our ships multiplied and their enterprising skippers sailed them to the remotest ports of the seven seas. In spite of the British Embargo Act of 1808, matters went so well with our Merchant Marine that in the year 1820 only eight per cent of our foreign commerce was carried in foreign ships. To-day, nearly a century later, the situation has been so completely reversed that only eight per cent of our large and rapidly growing foreign commerce enters the ports of this country under the American flag.

The decadence of our over-sea shipping is due to more than one cause, but there can be no doubt that the first and most vital blow against this industry occurred shortly after the war of 1812, when several reciprocal treaties were made with the leading maritime nations, under which it was agreed to levy the same duty upon American as on foreign ships. In spite of this withdrawal of Government aid, the owners and masters and the excellent crews of that day carried on the competition so successfully that during a period in the middle of the nineteenth century preceding our Civil War the Merchant Marine of the United States took precedence of every other not merely in tonnage, but in the speed and weatherly qualities of its ships and the fine seamanship of the men who sailed them.

It was when our Merchant Marine was at the zenith of its prosperity that two developments of great significance, one political, the other industrial, were in progress which were, ultimately, to sweep our flag from the high seas. The Civil War completely disorganized our deep-sea carrying trade. The sale and transfer of American ships, the depredations of the Confederate cruisers, and the withdrawal of our merchant ships for cruiser and transport service in the South combined to strike a terrible blow against our maritime interests. From this, however, we might have recovered, had it not been for a momentous industrial change, which proved even yet more fatal. This was the coming of the age of iron and steel and the substitution of these materials for wood in the construction of ships, for we were without either the materials or the facilities for steel ship construction. Great Britain, on the other hand, had both. At once, under the altered conditions, that country began to move forward to the absolute supremacy which she has since established; on the other hand, our marine industry, already staggering under the blow dealt by the Civil War, continued steadily to decline. After the war the opening up of the West by the construction of railroads and the development of the vast internal resources of the country, offered so promising a field for capital that a national indifference and neglect was added to the other destructive causes above enumerated. Also the great demand for highly paid labor in the interior of the country robbed the sea of its one-time attraction, and in ever increasing numbers our young men turned from the forecastle to the machine shop and the factory.

Something has been done toward the resuscitation of our shipping by the admission of materials for shipbuilding free of duty, but further measures are necessary. There still remains the great difference in wages and general cost of operation, and something should be done by the Government to offset this. At the present writing it looks as though the needed relief could be found by a return to the successful plan adopted by the First Congress, and allowing a moderate rebate on all goods imported in American bottoms.

The Car of 1913

ALTHOUGH there is a greater difference in automobiles generally this year than there ever was before, it is not of the kind that the average person has as yet come to know or to realize. In other words, it is not so much a difference in lines or appearance—this year's cars will appear much the same as their predecessors—as it is a deeper rooted difference that reveals itself in greater efficiency, greater stamina and greater wearing qualities. The difference between goodness and mediocrity lies now, more than ever, in detail rather than in general.

The use of a better grade of materials, primarily, is responsible for the improvement. The design and construction of present-day cars would seem to indicate that the factor-of-safety bugaboo, which has necessitated comparatively massive construction, to the detriment of car efficiency, has been silenced for all time. True economy, apparent in the use of comparatively expensive vanadium and other alloy steels, rapidly is coming to the fore, and that it has had a beneficial effect in simultaneously reducing weight and increasing strength scarcely can be denied.

Latterly, vanadium has been alloyed with iron for cylinder construction, thereby directly increasing engine efficiency by reducing the ratio of weight to power. It is much the same with copper and aluminum alloys; great strides have been made in metallurgy during the comparatively short space of time embraced in the past twelvemonth, and though it may cause some a pang of regret that progress of the kind is more or less obscure and is not directly convertible into capital through the medium of exhibition, it nevertheless represents the sound foundation upon which reputations are built, and, incidentally, it illuminates the dividing line between the good cars of yesterday and the better cars of to-day.

Design, too, has made strides that are not to be disputed. There is a marked tendency toward the greater rigidity and simplicity attained by the method of casting cylinders in a single block; the integral casting of intake and exhaust gas passages is only one of the plainly visible evidences of successful attempts at better construction. More attention has been paid to the generally recognized necessity for segregating the magneto and the carburetor in order to reduce the hazard of fire, and as a rule ignition apparatus has been more carefully located where it is less exposed to the insidious action of dirt and water.

In the construction of engine components, the careful attention which has been given the lightening and balancing of reciprocating parts has played an important part. Pistons and connecting rods now are considerably lighter than they were. In the majority of factories, crankshafts and even flywheels are carefully balanced, both statically and in the running balance machine which has come into extensive use only within the past year and which has been of recognized value in detecting and directing the correction of faults that result in vibration. Notable advances have been made, also, in the design of valve mechanism, which now is quieter than ever before. Cam shapes remain practically unchanged, though the increasing use of spirally cut gears and silent chains in camshaft driving mechanism has permitted a nearer approach to silence and rendered valve action more positive.

The passing of many city ordinances prohibiting smoke has necessitated the perfection of lubricating systems, and with the perfection automatically has come greater efficiency; oil bills have been cut virtually in halves. The trough system, originally developed for use in Knight type engines, is coming into vogue for poppet valve engines, and auxiliary throttle-controlled systems have been adopted by several prominent manufacturers.

What has been said with regard to the lightening and balancing of engine parts applies with equal force to the clutch. The use of pressed steel parts for cone clutches, which type still appears to be the favorite, has materially lightened the *ensemble* without reducing strength. The lightening, of course, has reduced the tendency to "spin" and in this way has operated to reduce the wear and tear on transmission elements. Spring inserts, which insure against gripping and slipping, are used quite as much as cork inserts, and both are far more popular than they were last year.

Change gear sets have suffered but little alteration in their material aspects. Four forward speeds, however, instead of three, are used to a greater extent than they were, and their advantages no longer are confined to high-priced, or even moderate-priced, cars; several manufacturers whose products list at less than $1,300 have announced four-speed gear sets for the first time this year, thus probably marking the forerunner of their more general adoption for low priced cars. The importance of the metallurgist in the treatment of gear steels is another factor which likely will be realized some years hence, when the gears in 1913 cars are still doing duty and the gears of yesteryear have passed away.

There are just two other things wherein even a casual glance will serve to convey the marked superiority of the 1913 car. The first of these is the noteworthy reduction of rattles and squeaks, which have emanated from brake parts, fenders and springs, and the other is the completeness with which the newer crop of cars is equipped. The former can be attributed only to better construction, and the latter is but the natural outcome of steadily growing demand.

A National Aerodynamic Laboratory

THAT aviation has made the advances it has in this country is very rightly a source of wonderment, because the inventor, the designer, and the builder have all had to grope their way, trusting to incomplete experiments and to empirical formulæ that left much to be desired. Aviation has undoubtedly come to stay, but we have still much to learn before it can be classed with yachting so far as risks are concerned; but fortunately this information can be obtained in a national aerodynamic laboratory without hazard.

The part the model experimental basin has played in the successful evolution of modern ships is a matter of general knowledge. Enormous economies have been effected and the science of naval architecture is advanced. These results have been the substantial return for fairly modest investments. In brief, they have supplanted the rule of thumb and the guesswork of other days. Kindred work is that of the aerodynamic laboratory. A number of European nations have established plants of this sort to their undoubted advantage.

The need of similar facilities in this country has been forcefully urged by Capt. Washington I. Chambers, U. S. N., who is in charge of aviation in our navy. To quote Capt. Chambers:

> "Little more than a year ago our knowledge of the effect of air currents upon aeroplane surfaces was almost entirely a matter of theory. The exact information available was so meager that aeroplanes were built either as copies, slightly modified, of other machines, *or else by way of haphazard experiment*. This state of affairs obtains to some extent in the United States to-day, although in Europe aeroplane construction is now largely based on scientific data obtained at notable aerodynamic laboratories. The intuitive, hasty and crude methods of the pioneer cannot succeed in competition with the accurate and systematic methods of the scientific engineer, and it is beginning to dawn upon our perceptions that through lack of preparation for the work of the scientific engineer, i. e., through delay in establishing an aerodynamic laboratory, a waste of time and money, a decline of prestige and an unnecessary sacrifice of human life have already resulted."

A national aerodynamic laboratory, such as our naval aviation expert recommends, might well be located in Washington, where many established facilities could lend their aid and the rest of the needful plant could be provided at a cost of probably not more than $200,000. Such an institution, presided over by broad-minded men, would be a benefaction to everyone either directly or indirectly interested or concerned in the promotion of aerial navigation.

The work of such a laboratory would logically divide itself into two main divisions: experimental verification, and experimental research. The first would deal essentially with problems as they stand and lead to the formulating of certain standards, but unquestionably the most valuable results would be the fruit of research work prosecuted continuously, systematically, and patiently in the thorough and precise investigation of new ideas or of old ideas with new applications, and in this way discovering general laws and formulæ. In the language of Capt. Chambers this order of procedure "is the short cut to substantial efficiency, economy, improvement, and prestige."

It is not necessary here to mention the apparatus or particular equipment which an aerodynamic laboratory should have. The plant of M. Gustave Eiffel at Auteuil, the trial track at St. Cyr, France, the laboratory of the Italians, the facilities of the Russians at Koutchino, and the splendid German and English institutions show us what we must have. Our own inventive resourcefulness will probably suggest developments. Aviation will mean in the air just what the evolution of the automobile has meant in daily life on the ground, and its adaptations will be quite as varied. Of course, the fighting man is primarily interested in that field, and so is our citizenry, too, because it has already been shown that of two battling countries, the one that has a superior aerial fighting force will surely hold a very great advantage. This is not the prophetic conclusion of the enthusiast, but the actual fact as proved by the results of the Balkan uprising.

Congress saw fit to establish our model experimental basin at the Navy Yard in Washington. Let us trust that the same legislative wisdom will provide a national aerodynamic laboratory. The cost will be modest, but the results will be invaluable.

Electricity

Electrically Operated Suspended Railway.—A novel way of mountain climbing is provided in the new electric suspended railway up the Kohlererberg, in the Tyrolese Mountains. The suspension cables, 5,400 feet in length, are carried on twelve steel supports, and two cars each accommodating fifteen passengers and the driver are operated, one being hauled up the hill by duplicate traction cables while the other is descending. Complete safety appliances are provided, and a magnificent view is opened out as the car rides steadily and smoothly up the 2,760 feet from the Eisack in thirteen minutes.

Picture Telegraphy Across the Atlantic.—Although the Berlin scientist, Dr. Korn, is having good success in sending photographs by wire between stations located at Paris, Berlin and Monte Carlo for use in press work, he wishes to apply his method over a much longer distance. In fact, it is possible to send the photographs by mail between Paris and Berlin, for instance, in a comparatively short time, so that the newspapers are not as likely to take up a picture-transmitting scheme as when they are a long distance from the center of events. For this reason he expects to take up the question of operating upon the Atlantic cable and is confident that he will be able to send photographs across the ocean. He is also considering the matter of coming to America in order to apply the system to a line between New York and San Francisco. We illustrated this apparatus not long ago.

Electric Stage Service Across the Alps.—Quite an extensive project is being organized in Switzerland for an electric automobile service across the Alps, and the cost of improving the roads and purchase of material is about half a million. The line runs from Airolo by way of the Bedretto valley and the Nufnen pass, ending at Ulrichen in the Valais region, with a total length of 25 miles. Considerable work will need to be done in enlarging the routes so as to make them suitable for automobile traffic, and a bridge is to be built over the Tessin River. The new electric automobiles have capacity for 22 passengers and make the trip in 2¼ hours on ordinary and 1¾ on express service, running at 12 to 22 miles an hour. There are eight to ten stations along the route and three trips are made per day in each direction, during all seasons when there is no snow on the roads. A great success is predicted for the electric line.

How a Paris Central Station Gained by the Change to Greenwich Time.—The fact that Paris adopted Greenwich time not long ago causes an electric-light station to gain $20,000 a year, according to an estimate. The reason for this somewhat curious result lies in the difference of time of burning electric lamps and even though this is very small, it figures up in a yearly estimate to quite an extent. Greenwich time of 5 o'clock corresponds to 5.10 Paris time, for instance. Lamps are turned on according to the amount of daylight, but offices close at a fixed hour. Should an office close at 6 o'clock, it is evident that the lamps will have burned 10 minutes longer owing to the change over to Greenwich time. The extra amount of current is naturally paid for by the users, so that this makes the central station gain about 1 per cent, and even this small difference applied to the case of an electric plant furnishing 15,000,000 kilowatts a year, will give the above increase.

Cableway to the Col du Midi.—A suspended cableway is now building on Mont Blanc and it will reach the elevated point of the Col du Midi, which is not far from the summit. It follows somewhat the general lines of the Wetterhorn cableway and like the former it is designed on the Ceretti-Tanfani system. The terminus of the cableway is on the Col du Midi, 11,700 feet high, this being somewhat below the well-known peak of Aiguille du Midi, (12,600 feet), but the latter was rejected in favor of the former owing to lack of space at the peak to make a suitable landing place. The car hangs down from a roller carriage traveling on a single main cable which is stretched along the route upon structural iron towers. There is an upgoing and a downgoing car as in a cable incline, the car being drawn along by a cable working upon sheaves at each end. What is novel is the use of an extra cable running along under the main cable and passing through the carriage. Usually it runs idle, but should the main cable break, it then serves to support the carriage by a set of rollers so as to take the place of the former and the car can still run. Should the towing cable break, on the other hand, the extra cable now serves to draw the car into the station, thus playing a double part in accidents. The line is about 3 miles long in horizontal projection and starts from the Pelerins station at an altitude of 3,400 feet, and ending at the Col du Midi 8,300 feet higher. The lower end lies near Chamonix, and the railroad runs quite near this point. It is laid out in four sections to avoid using too long spans, so that passengers change cars three times. The maximum length of span allowed is 2,300 feet on account of the strain on the towers. The second station is at La Para and the third at Bossons glacier. It is proposed to run an automobile service to bring tourists from Chamonix to the lower station. One section of the cableway is nearly finished and the whole will be running in 1916.

Science

The International Union for Solar Research, which last met on Mt. Wilson, Cal., in 1910, will hold its next meeting at Bonn, beginning August 1st, 1913.

An Oyster-shell Building.—A five-story concrete building, the concrete being made of oyster shell from the reefs of Galveston Bay, has been erected at Galveston, Texas. The owners of the building and its constructors, Nic Bohn and G. Tietze, claim this material is better and cheaper than concrete made with gravel. Shell concrete built into a wall 3 feet high and 336 feet long in 1882 withstood the severe test of fire and water and is to-day as sound as when built. It is estimated that the shells of 5,896,000 oysters are imbedded in the walls of this building. This is said to be the only building of its kind in the world.

The British Association for the Advancement of Science will meet in Australia, for the first time, August 1914. The Association has met three times in Canada, and once in South Africa, but all the other meetings have been held in the British Isles. The Australian meeting will include sessions at several towns. The commonwealth government has appointed a federal council to arrange for the meeting, under the patronage of the governor-general and with the prime minister as chairman, and has granted £15,000 to pay the passage to Australia of not fewer than 150 official representatives. A number of foreign men of science will be included in this number.

Effects of Indol in Producing Symptoms of Senility.—Some interesting experiments as to the effect of the chemical compound indol in producing sclerosis have just been conducted by a pupil of Metchnikoff. Indol is one of the toxins secreted by intestinal bacteria, and Metchnikoff has claimed that it was responsible for certain symptoms of senility. In the experiments referred to doses of 0.04 gram of indol were injected into guinea-pigs. Not only was sclerosis of the aorta observed, but the liver, kidneys, and suprarenals were affected and there was a tendency to hardening of the brain. Since these are all symptoms of age, Metchnikoff's theory seems thus far supported.

The Electrical Resistance of Trees has been made the subject of some elaborate experiments by G. E. Stone and G. H. Chapman at the Massachusetts Agricultural Experiment Station. It was previously known that trees possess relatively high resistance—an important quality as serving to protect them from lightning—and that the resistance varies for different kinds of tissues. Messrs. Stone and Chapman's investigations reveal the further fact that the resistance varies markedly with the temperature, being higher with a low temperature and lower with a high temperature. This fact results in a diurnal and an annual period in the resistance. The cambium layer shows the least electrical resistance. This is followed by the phloem and the sapwood.

Aeronautical Weather Station in England.—The British Meteorological Office has arranged to operate a branch of its service at the Royal Aircraft Factory, South Farnborough, for the purpose of supplying meteorological information and forecasts in a form directly applicable for the guidance of airmen, and also for carrying on investigations of meteorological problems for the Advisory Committee on Aeronautics. Mr. J. S. Dines has been appointed meteorologist in charge. The equipment will include pilot and sounding balloons and laboratory appliances, in addition to the ordinary meteorological apparatus. Special forecasts and warnings for aeronauts will be issued on the basis of information telephoned from the Meteorological Office at South Kensington.

The Economics of Mountain Snowfall.—The attention of American meteorologists has been directed in recent years to the great importance of the winter snowfall in the mountains of semi-arid western states as a source of the water available for agricultural purposes or for motive power the following summer. A dual problem has been under investigation: (1) the development of methods of measuring the volume of snow lying on the mountain slopes, as a means of predicting the amount of water it will yield, and (2) the conservation of the snow by appropriate treatment of the forest cover. Among the interesting discoveries made in this connection is the fact that the ideal forest for snow conservation is one filled with glades whose area bears such proportion to the height of the trees that, while snow enters freely, the wind and sun cannot reach the bottom. The production of such glades by cutting and pruning, as well as by planting trees of suitable species (e. g., the mountain hemlock), becomes, therefore, a part of forest practice in the regions in question. Aside from investigations by the Weather Bureau and other government institutions, this subject has been most actively studied by the excellent meteorological department of the University of Nevada, which is now planning to offer a special course for foresters on the relation of mountains and forests to the conservation of snow. An adjunct of this university is the well-known meteorological observatory on Mount Rose.

Automobile

International Automobile Shows.—International exhibitions of automobiles have been planned [illegible] 11th to 22nd, in Brussels, Belgium, and for the months of March, April and May in Vienna, Turin, Budapesth, St. Petersburg, Berlin and Stockholm.

The Footstool-lunch Basket.—By way of killing two birds with one stone, so to speak, an enterprising accessory manufacturer has developed an automobile lunch basket which serves a dual purpose in that it is a footstool as well. The basket proper is made of wicker-ware and is fitted with the usual knives and forks, cups and saucers, etc., with a liberal space for the storage of food. The top is slanting and strong and is covered with leather to resist wear. It is designed to be placed in the tonneau.

The Deep Cushion.—Just where the deepening of cushions will end, unless it ends on the floor of the car, no man can tell at present. When ten-inch cushions were advertised as the acme of perfection, enterprising manufacturers almost immediately announced twelve-inch upholstery and two more lately have gone to the length of providing cushions no less than fourteen inches in thickness. The saving grace of an otherwise ludicrous situation is that the deepening of cushions in general has had a distinctly beneficial effect—for the car owner, of course.

Guessing at Speeds.—Demonstrating the deceptive nature of speed judging by sight alone, the results of a test recently held by a British automobile club are interesting. Several motorists were lined up on an unfrequented road and required to estimate the speed of a car driven at a predetermined rate with the aid of a speedometer. Out of four trial runs at various speeds only two speeds were guessed by one person correctly. The others varied from the correct speeds to such an extent as to emphasize very forcibly that it is practically impossible, without extensive practice, to judge of the speed of a car merely by watching it pass.

"Clean Design" in Cars.—"There are no kinks, no corners nor gable-end projections at dash or elsewhere," advertises a well-known foreign manufacturer in bringing to public notice his latest creation. Which, briefly, is exactly what the present American car accents. Never before has the striving for "clean design" been so apparent in American products. Unsightly tool boxes which heretofore have cluttered up running boards have been relegated to places of less conspicuousness and the "blending" of lines at dash and at tonneau is a marked contrast to the angles and generally unfinished appearance ushered in with the adoption of front doors.

The Long-stroke Motor.—Imported from abroad, where it flourished long before it got to America, no waning is apparent in the popularity of the long-stroke motor. From a conservative middle ground, manufacturers apparently are getting to the extreme in stroke to bore ratios and the wisdom of the practice well may be doubted. Among the later developments announced for the coming season, are two motors from the same manufacturer, one of which measures $3\frac{3}{8} \times 6$ and the other measures $4\frac{1}{4} \times 7$. It is true that motors with even longer strokes than these have given a measure of success abroad and they therefore cannot be viewed wholly in the light of experiments. Time only, on the road, in the hands of owners, can tell just how much the designer has bettered existing conditions by his plans.

The Filled Tire.—Periodically, almost continuously, the cellular, spongy or gelatinous tire-filling compound which is expected to replace the air in pneumatic tires makes its appearance, floats for a moment in the public eye and then fades away into the future. But it must not necessarily be assumed that such will always be the case and that success in this direction never will be obtained. The repeated resurrection of the idea shows the existence of a latent demand and it is quite within the bounds of possibility that the demand may some day be filled. Already there are several such compounds on the market which are giving a measure of success and in them their manufacturer, or compounders, would seem to have eliminated many of the difficulties which at first were experienced with everything that was supposed to take the place of air and banish tire troubles forever.

Wire Wheels.—Despite the fact that the automobile undoubtedly has reached a noteworthy plane of efficiency and dependability there can be little reason to suspect that finality of design has been reached. There are few manufacturers who have not something new to offer either in the way of equipment or design that has been slightly altered still further to increase efficiency and to reduce the small amount of physical labor necessary in the operation of any car. More than ordinarily prominent among the changes which will be evident in the car of 1913, and which can be listed under the heading "tendency in design," is the widespread movement in favor of wire wheels. Already more than a score of manufacturers have specified wire wheels as optional equipment and three or four have taken the bull by the horns, in a manner of speaking, and have specified wire wheels as standard equipment, with wooden artillery wheels optional.

In outward appearance the "car of the future" resembles a submarine boat more than it does a carriage. Its long cigar-shaped body incloses everything except the wheels, and even they are covered for almost half of their diameter

The Future Car

How Car Bodies Have Developed at Home and Abroad

By Walter Baunard

In automobile designing as well as in political movements coming events cast their shadows before them. If we would visualize the car of the future, we have only to study the car of the past. That is the object of this article. In order to obtain a correct impression of the automobile of the future, the author has presented and criticised both the European and American cars designed during the last twelve years.—EDITOR.

THAT the first automobile bodies were in all respects nothing but adaptations of the older carriage bodies is fairly well known. Many of the readers of this periodical will remember the first cars of a dozen years ago, and their awkward appearance. They were the product of a compromise—and like most compromises, were very unsatisfactory. That the motor driven carriage was a thing apart and different from the horse-drawn rig early became evident to thoughtful designers of automobile bodies. But while they well realized the necessity of striking out in different directions, they were not at all anxious to make radical innovations. The conservatism of the majority of the human race resents upheavals of any kind, preferring rather a gradual elimination of the undesirable. The change from carriage body to automobile body therefore had to be made slowly, and at the present time we have about arrived at the half way station. The automobile of the future will look no more like the motor car of to-day than the limousine of 1913 looks like the *dos à-dos* of 1896. The limousine or torpedo touring car of the present year is but a link in the gradual transformation of the horse-drawn buggy into the completely enclosed, dust proof, silent and comfortable "car of the future."

In outward appearance the "car of the future" resembles a submarine boat more than it does a carriage. Its long cigar-shaped body incloses everything except the wheels, and even they are covered for almost half of their diameter. To the eye of the motorist of 1913 it may present too "squat" an appearance, owing chiefly to the low position of the body. The car has no running boards, no hood, no mudguards, no wind shield and no flapping top. The motor is carried in front of the driver, as in the ordinary motor car, while the various indicators are placed within easier reach of the driver's hand than is possible in the orthodox vertical or sloping dashboard arrangement. The curved plate-glass front of the body affords a clear view of the road ahead, while giving absolute protection from wind, dust and rain. Ventilation is achieved by narrow slits in the sides and top of the car. Conforming to the shape of the body, the doors are curved, reaching so close to the ground that an eleven-inch step is all that is necessary to enter the car. Ample space is provided in the rear of the hollow body for baggage and the carrying of spare tires and other parts, while the seating arrangements allow each passenger more room than he would have in a modern limousine, and far more than in the various seven-passenger models of the present day. Wind resistance and the danger

Fig. 1.—Car built for the German Emperor in 1903. It had a rear entrance, proof that the problem of efficient mudguards and running boards had not yet been solved.

Fig. 2.—A car designed for the German Emperor in 1905. There are still unmistakable signs of the carriage maker's hand

Fig. 3.—The German Emperor's 1907 car. Although it would not attract much attention to-day, the seat backs are stiff and vertical, the upholstery hard and thin. The driver has no protection.

Fig. 4.—A touring car of 1909

Fig. 5.—A splendid car built in 1910 for the President of France. Fore doors appear for the first time

Fig. 6.—A 1912 model, which, were it not for the presence of the tool box in the very middle of the running board, might be considered more beautiful than the graceful car shown in Fig. 7

Fig. 7.—A 1913 German model, a good example of neat designing

Fig. 8.—A 1906 American limousine.

Fig 9.—A 1907 American landaulet

Fig 10.—The few changes made since 1907 caused many to think this 1909 model the "car of perfection."

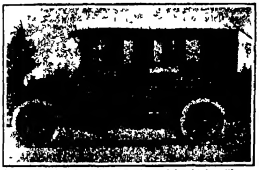

Fig 11—An American 1911 model which will not survive because of its peculiar broken appearance.

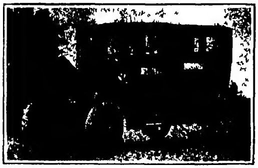

Fig 12.—This type of 1912 is objectionable for the reason indicated in connection with Fig 11

Fig 13.—A coupé type of 1913, which looks odd because the hood and dash-cowl combined are longer than the car body

Fig. 14.—A so-called brougham, designed in America, in which it is difficult to pick flaws.

of skidding are reduced to a minimum in this design, and a number of racing cars constructed on these lines have proven that greater speed can be attained. The tendency toward "stream line" bodies is clearly evident although opinions differ as to the ultimate design which will be evolved. To assist the reader in forming his own opinion of what the car of the future will look like I am showing herewith types of body construction in chronological order from 1903 to 1913.

The cars shown in Figs. 1, 2 and 3 were made for the German emperor in 1903, 1905 and 1907, respectively, and therefore may be said to represent the best type of these years. The first two are "rear-entrance" cars, built in this manner chiefly for the reason that the problem of efficient mudguards and running boards had not yet been solved. They are clearly attempts at producing something comfortable and suitable for motor propulsion, and still suggestive of the carriage maker's hand in the design. The manufacturers of the chassis and motors were already striking out in new directions at that time, but the body builders were still hampered by the traditions of the carriage industry

Fig. 3 shows a car which resembles the machines of to-day It could be driven down Broadway in New York city without causing sarcastic remarks among the pedestrians. But the backs of the seats are stiff and vertical the upholstery is hard and thin and the driver has no protection from the elements and the dust

The next illustration represents an immense step forward It is a splendid car built in 1910 for the president of the French Republic by a firm which supplied Napoleon with his court carriages more than a century ago It shows the fore-doors for the first time When professional chauffeurs did the bulk of the driving of motor cars, no one gave much attention to their comfort and convenience, but as soon as the private owner began to drive the car himself the necessity of doors for the front part of the car became evident A comparison with the preceding photographs shows some of the most characteristic and pronounced tendencies of that year The wheel base has grown longer, the steering column is set at a more 'rakish' angle, the steering wheel is larger in diameter the running boards are free from unnecessary boxes and litter of all kinds, and the whole car has more sweeping and pleasing lines.

Particularly graceful are the lines of the huge limousine shown in Fig. 6 Were it not for the presence of the tool box in the very middle of the running board, it might be considered a more beautiful car than the graceful model represented by Fig 7 The cars were built in 1912 and 1911 respectively—that is to say, they are the leading models of these years. The sweeping curve at the rear of the top in the 1912 model is undoubtedly more pleasing than the sharp edge of the following year's type, but the neat outlines of the mudguards and hood, the lower steering column and especially, the clear running boards are advantages which the earlier model does not show

The American automobile industry during those years kept fully abreast of its European rival The same faults and drawbacks are noticeable in both but there are also in evidence all the little improvements that were added abroad, in addition to some that were invented on this side of the Atlantic But for the peculiar construction of the body of the 1911 model in Fig 11, which makes it resemble two independent carriage bodies, stuck together as a sort of afterthought there is no need of apology on this maker's part The type is one which has a number of adherents, but which will not survive just on account of this peculiar 'broken' appearance. In more exaggerated form it is shown in Fig 16, which is a fine illustration of how an automobile body should not be designed. This style of construction is positively ugly—despite the fact that it may be comfortable and mechanically advantageous The car also appears bigger than it really is, which may or may not be desirable, according to the opinion of the purchaser The coupé type shown in Fig. 13 looks so odd chiefly on account of the extreme length of the hood, covering the six-cylinder motor, the hood and dash-cowl combined being longer than the entire body of the car

It is difficult to pick flaws in the construction of the body shown in Fig. 14—a so-called brougham. The first view of this car impresses one with the immense power and speed possibilities lying within it, and subsequent closer examination only strengthens this first impression. It is a body design which is in no way inferior to anything produced in Europe, and shows the present high state of the industry in this country The wheel-base of this car is practically thirteen feet.

An extraordinary European body construction is shown in Fig. 15. This type represents the latest idea in inclosing everything within the outer lines of the body, presenting a perfectly smooth exterior and greatly reduced wind resistance. Not only are the running boards absent, but the

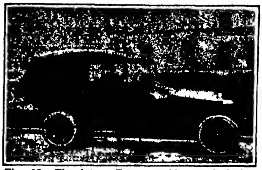

Fig. 15—The latest European idea in inclosing everything within the outer lines. Complete protection is afforded to baggage, spare tires and tools.

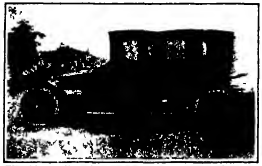

Fig 16—A French type of 1912, conspicuously ugly for its angles.

Fig 17.—A modern French roadster in which an attempt is made to obtain smooth lines.

Fig 18.—A good example of present French tendencies.

Fig 19.—A 1912 phaeton which has a distinctive body suggesting speed and comfort

body itself hangs over the wheels, giving plenty of room to the six passengers. The car is by all odds the most radical innovation in the line of body design, and from reports from abroad is expected to be placed in commission during the coming season by at least one prominent foreign maker. The car was shown built on an ordinary chassis at the last automobile show in Berlin, Germany, and created a veritable storm of discussion and criticism. It is the most comfortable design that has as yet been evolved, and the complete protection it affords to the baggage, spare tires, tool boxes, etc., is of great value to the long distance tourist.

French roadsters of peculiar shape are shown in Figs. 17 and 18, but a detailed description of their features is hardly necessary, as an examination of the illustrations will disclose their peculiarities.

The designing of bodies for motor cars is becoming more and more standardized. Only a few years ago body builders made a few special designs for each manufacturer and there were hardly any two of them alike. Then too the customer, particularly abroad, used to purchase his own bodies, made according to his preferences and ideas. The best example of this is the made-to-order car which some time ago was built for a wealthy American lady and which actually was measured so as to fit her figure as closely as possible. While other automobile purchasers were not quite so particular as to just how the body fitted them, they did express preferences which the body builder had to consider. As a result a number of freak bodies are now roaming this country as well as Europe. In many instances their owners are heartily weary of looking at them.

A standardization in body design, therefore, is very desirable not only from an economical standpoint as also from the more altruistic one of beauty—as opposed to freakish contraptions. It is cheaper to build one thousand good automobile bodies after one and the same design than it is to build one thousand mediocre ones after the individual designs of one thousand persons. Besides, the metal body is driving out the wooden body and it will not be long before the aluminium automobile body will reign supreme. In this country the use of metal bodies is increasing tremendously and the greater ease of manufacture, cheapness and practical indestructibility make them favorites with manufacturers demanding large quantities of bodies.

Many of the automobile manufacturers make their own bodies, in this country at least, and there is naturally an increasing tendency on their part to specialize on a few popular designs instead of pleasing each customer individually. In Europe it is still the custom in most cases to sell the chassis alone and have the customer order his own body attached. A much greater diversity among European cars is the result, and while this may appeal to some people it is decidedly uneconomical. At any rate one must admit that a manufacturer who makes it his business to design automobile bodies knows better what would suit a customer than the latter himself.

The trend of the trade, if examined carefully, shows the preponderance of four types of cars, and by gradual elimination of the various freaks and semi-freaks produced annually these four types will be generally accepted as standard for all cars and by all manufacturers. They are: The inclosed coupé for two and four people, the limousine for five to seven people, the race-about or roadster for two people and, finally, the open torpedo touring car for five to seven people. These four types cover the whole field and until the actual arrival of the "car of the future" will be found sufficient to meet all requirements.

Aeronautics and Aviation in 1912

THE year 1912 has witnessed greater development in aerostation and aviation than any other year since the heavier than air machine was introduced. Both sciences have been put to active military use by most of the large nations, and several nations have used dirigibles and aeroplanes to good effect in real warfare. At the end of 1913 it is possible that we shall have to record battles in the air. Just as last year there were several collisions, not all of which were fatal. At present guns for aeroplanes to use in attacking other aircraft are an established fact, one of the best of these being the invention of Lieut. Cleland Davis, U. S. A., while Lieut. Riley W. Scott has perfected a bomb-dropping apparatus that leaves nothing to be desired, and has won with it the Michelin prize of $15,000. He stands ready to deliver his device to any War Department that wants it and to instruct military aviators in its use. Lieut. Scott made a total of 8 out of 15 hits in dropping his projectiles from a height of 2,660 feet upon a 128 foot target.

The principal lines of aeroplane development last year were two: military and hydro-aeroplanes. England held a contest for military aeroplanes last fall like that held in France in 1911, while all the leading nations used aeroplanes in the annual maneuvers. At the close of the French maneuvers no less than 72 aeroplanes were reviewed by the Minister of War, and French pilots thought nothing of flying 360 miles a day during the war game. Flights totaling 43,000 miles were made in about a week's time. In the maneuvers in Connecticut and on the Pacific coast, Wright and Curtiss army biplanes were used. It was found possible to report to headquarters by wireless from a distance of 20 miles just what was occurring at the front. The chief difficulty experienced was the inability of the machines to carry two men—the first requisite of a military aeroplane.

After meeting with pronounced success the first of last year in the continuation of his hydro-aeroplane experiments at San Diego, Cal., Glenn Curtiss sent Hugh Robinson to the Monaco meet—the first hydro-aeroplane meet—in March. Robinson astonished the foreigners by his ability to navigate upon the open sea at Monaco. He had to compete only with a few other biplanes upon which floats had been hastily fitted. The result was that all Europe caught the "water plane" craze, and in the fall a number of hydro meets were held. At the Aero Club Show in the Grand Central Palace last May, Grover Cleveland Loening, the author of "Monoplanes and Biplanes," exhibited the first "flying boat," consisting of a monoplane, the body of which was watertight and formed a hull. He later made successful flights with this new craft. Donnet Lévêque, in France, applied such a hull to a biplane in which André Beaumont flew from Paris to Boulogne over water.

Curtiss brought out a similar flying boat and our Navy has recently purchased one. The advantage of this type of hydro-aeroplane is that it can skim the surface of the water at 50 miles per hour and make 60 miles per hour a few feet above the surface without the least danger to the occupants. As many as four persons have made a trip of an hour or more in a French flying boat. There has been but a single fatal hydro-aeroplane accident, and that was due to foolhardiness, as mentioned in a recent issue. One of these machines gives the double pleasure of flying and motor boating with the dangers of the former entirely eliminated. Wheels may be fitted for land use as well, if desired.

Aerostation in America received a severe set-back early in July through the bursting of what was practically her only dirigible. The "Akron" exploded early in the morning of July 2nd, while maneuvering above the shallow water of the inlet at Atlantic City. Melvin and Calvin Vanniman and the three other men that formed the "Akron's" gallant crew fell to their deaths. Melvin Vanniman, since his attempt at crossing the Atlantic with Wellman in the "America," had given his entire energy to the accomplishment of this feat. Finally, securing the financial backing required, he had constructed the "Akron" for this purpose, but while building her he made an improvement which consisted of weaving wire in the cloth forming the gas bag, so that the completed envelope was wirewound like the barrel of a wirewound gun. The gas bag would thus be strong enough to withstand the increase in pressure arising from heating and consequent expansion of gas. The envelope of the "Akron" Vanniman thought was strong enough to withstand a considerably increased pressure, and it is believed he allowed the pressure to increase when the sun came from behind a cloud, with the result that a weak section of the envelope gave way.

An equally appalling aviation accident that occurred on July 1st was the flinging out of her 70 horse-power Blériot monoplane of Miss Harriet Quimby and W. A. P. Willard, at the Boston meet. Willard, who was some distance behind Miss Quimby, was flipped from his seat probably as the result of suddenly developed gyroscopic force, and Miss Quimby immediately followed him. Both fell a thousand feet into shallow water and were killed. Miss Quimby shortly before, had won the honor of being the first and only aviatress to this day to fly across the English Channel. She used a 50 horse-power Blériot and made the flight from Dover to Calais in foggy weather. She landed at Hardelot 40 minutes after starting. Her accident at Boston would not have resulted fatally were two devices, which have since been perfected, been obtainable at that time. One of these is a gyroscope-compressed air automatic control for aeroplanes, which has been arranged to give automatic stability in all directions, and the other is a safety parachute of Japanese silk, weighing 6½ pounds, which is carried on an aviator's back like a knapsack and opens instantly when he is thrown out of his machine. Both are the inventions of Americans prominent in the electrical and aeronautic industries.

While there have been many long-distance aeroplane flights abroad, such as the 650-mile flight of Audemars in two days from Paris to Berlin, the only one of note in America was the 1,500-mile trip of Anthony Jannus from Omaha, Neb., to New Orleans in a Benoist hydro-aeroplane. Jannus' flying time was 31 hours 43 minutes. He stopped at many towns en route, and gave exhibition flights. The 471 miles from Kansas City to St. Louis were covered by Jannus alone in 9 hours 28 minutes, which is one fourth faster time than the express trains make. The 1,080 miles remaining were covered with a passenger and an 85-pound case of beer. The journey was made without any serious accident, the winding rivers being followed the entire distance. The replacements to plane and engine did not amount to $20.

All speed records were broken in the Bennett Cup race at Chicago on September 9th, when Vedrines, on a 140 horse-power Deperdussin "monocoque," covered the 124.8-mile course in 1 hour 10 minutes 57 seconds at the rate of 105½ miles per hour. He covered 10 kilometers in 3 minutes 27 3/5 seconds, or at a rate of 107.68 miles per hour. The American monoplane with 160 horse-power Gnome motor, built to defend the cup, was never flown.

As for the duration record, this was again raised by Fourny on a Maurice Farman biplane from 11 hours to 13 hours and 18 minutes on September 11th. A distance of 628 miles was covered over a 10-mile circular course. In America Lieut. John H. Towers, on October 6th, made an endurance record of 6 hours and 10 minutes with a 75 horse-power Curtiss hydro-aeroplane, while on October 31st Walter E. Johnson, at Bath, N. Y., carried a passenger for 3 hours 51¼ minutes with his Thomas biplane fitted with a 65 horse-power Kirkham 6-cylinder motor. The greatest total distance covered across country in a single day was the 570 miles between Valenciennes and Biarritz, traversed by Pierre Dancourt in his 50 horse-power Borel monoplane also on October 6th.

Three notable altitude flights were made the latter part of the year, two by Garros and one by Legagneux. The record was raised each time 1,000 feet or more. Garros now holds it with 5,601 meters (19,032 feet), subject to revision. He made the record at Tunis and then flew to Sicily—160 miles oversea—and thence to Italy and Rome—a total distance of 700 miles. This was the most daring over-water flight since Lieut. Bague was lost.

The international balloon race started from Stuttgart, Germany, on October 27th. The race was won for France by MM. Bienaimé and Rumpelmayer in the balloon "Picardie." A landing was made near Moscow, and a new record of 1,364 miles was set up. Leblanc was second with 1,240 miles, and John Watts of St. Louis, third, with 1,000 miles.

The acquirement of aeroplanes by our Navy will probably be rapid from now on, since Capt. Charles deF. Chandler has invented a catapult, making it possible to successfully launch an aeroplane from the deck of a battleship. The Navy already has four hydro-aeroplanes, and one flying boat in addition to eight or ten biplanes possessed by the Army. Recent experiments with the Navy hydros have shown that submarines can be easily located when completely submerged even in rather muddy water. The wreck of the American warship "Philadelphia," which stranded off Tripoli in 1802, was recently discovered from an aeroplane.

Future biplanes purchased by the Government are all to have monoplane bodies of streamline form, bodies similar in many respects to that of the Benoist biplane used by Jannus. The twin motored and duplicate twin propellered Wright biplane which the late Howard W. Gill was to have flown in the Gould SCIENTIFIC AMERICAN $15,000 two-motor prize contest on July 4th last, also had a body with aviator's seat therein. The above event was declared off as Mr. Gill was the only entrant ready to appear at the stated time and place. In England lately successful flights have been made with a two-motored biplane, and Grahame-White expects to fly to America in 30 hours next summer with a machine fitted with four motors of 250 horse-power each. The idea promulgated by Mr. Edwin Gould has, therefore, fructified.

Subsidizing the Motor Car

WITH a view of calling them out for mobilization, the French as well as the German government allows annual subsidies to owners of power wagons, provided these are of the approved types according to the War Department specifications. The leading constructors are now building their wagon trucks with this end in view, and this leads to a standardising of the chassis as regards certain general sizes and other features, not interfering, however, with individual construction. The rules call for a 4-cylinder motor in all cases, and the preferred type carries about 3 tons load. Strict rules provide that the French cars shall be built entirely of home material. The 3-ton car receives a first subsidy known as purchase subsidy of $600 and an upkeep subsidy of $200 during 3 years following. In Germany the 5-ton wagon has subsidies of $1,000 and $250, respectively, for the same cases. Great Britain is now entering the movement, but the subsidies, $40 to $60, and $75 annual are much smaller. Austria has a similar system.

Wanted: A Small Gasoline Plow

To the Editor of the SCIENTIFIC AMERICAN

The above heading being made by one Mr E M Bleakslee, and answered from the standpoint of the owner and operator of a gasoline outfit of this sort in the December 7th issue of the SCIENTIFIC AMERICAN, I have a few suggestions to offer (being a student of mechanics in general) that might be useful.

Now, to get at the root of the thing A small gasoline plow to be economical should essentially be light in weight and of corresponding small horse-power, so that fuel would not be too costly But it must have as great tractive power as possible. Therefore, I believe that the novel traction wheel and tractor described in the SCIENTIFIC AMERICAN of September 7th, 1912, comes nearest solving the problem It comes under the heading "Novel Italian Traction System"

Porterville, Cal. ALBIN A ANDERSON

The Gyroscopic Effect of Motors

To the Editor of the SCIENTIFIC AMERICAN

In re this discussion as to the gyroscopic action of rotary motors, and especially as to aviators' experiences in the matter, the writer has come across the following footnote bearing on the question in a pamphlet entitled "Cantor Lectures on Aeronautics," by Charles Cyril Turner, being some lectures delivered before the Royal Society of Arts in 1910

"It appeared subsequently, however, that with this rotating motor working at greater speed, it has a gyroscopic effect, and Delagrange, shortly before his fatal accident, told his friend, M Gasnier, that it kept the machine so rigid that he found it almost impossible to alter his course by moving the elevating plane, and that in order to descend he had to slow the engine slightly C C T"

It would appear that any danger due to the gyroscopic action of rotary motors—and also propellers would exist only with very sudden changes of direction, such as might be caused sometimes by a sudden upward downward or sidewise wind-gust striking only part of the aeroplane or different parts at different moments, and that the aviator would rarely if ever change the direction of movement suddenly enough to bring this gyroscopic force into dangerous play, for it is well known that gyroscopic force increases with the square of the speed with which the plane of rotation is changed

It would also appear that gyroscopic force could be put to good use in steadying or even balancing a flying machine by producing a balanced effect with two or three sets of revolving motors—or motors and propellers—situated in both horizontal and vertical planes, each set consisting of two revolving in opposite directions, while one set of vertically revolving motors might extend fore and aft and the other transversely of the machine It would be interesting, at least, to see these things tried

Livermore, Cal. ELMER G STILL

The Gyroscopic Action of Gnome Engines

To the Editor of the SCIENTIFIC AMERICAN

I should like to make a few remarks on Mr Earle L. Ovington's letter published in your issue of December 7th on the death of Paul Peck and gyroscopic force in an aeroplane using an engine of the rotary type

In his letter Mr Ovington asks if anyone has ever heard of an aviator who has really had experience with a rotary motor complain about its gyroscopic action Of course Mr Peck is dead and it would be a very easy matter for anyone so desiring to credit statements to him which he might have or might not have made Mr Ovington makes the statement that it was a fact that Mr Peck was never aware of any gyroscopic action According to him, therefore, it must be so, but it might be a good idea to hear from another aviator on the same subject. A few days before Mr Peck was killed Mr John D Cooper, licensed pilot No. 60, questioned him in regard to his motor, and especially in regard to any gyroscopic action that it might develop. Mr Cooper had never flown with a rotary motor, but was considering the buying of one. Naturally he was desirous of learning all about them from an aviator who had had considerable experience with one.

Mr Peck told Mr. Cooper that in making a turn he did feel the gyroscopic action of his motor, and especially if he was making a spiral. He said that in making the first turn he only felt the action slightly, but that in the second turn it was very strong, and that he seldom dared complete the third circle of the spiral. It was undoubtedly in making more turns than his judgement had heretofore advised him to make, owing to the gyroscopic action, that he lost control of his machine and the sad accident occurred which resulted in his death For we all know that it was in making a spiral that he met his death, and that the machine never seemed to come out of its steep bank the least bit during its descent, even though Mr Peck could be seen using his controls, trying to bring it back to a level position There can be little doubt about the gyroscopic action, about which he had spoken only a few days previous, having been too much for the controls of the machine once its full force was felt

I have every reason to believe Mr Cooper's statement in regard to his interview with Mr Peck

I cannot blame Mr Ovington for being so loyal to the type of motor that he has used most, for it is a poor kind of a sportsman who will not stand up for his favorite machine or motor and especially when it has won as much for him as his, for we all know that he flew more miles in 1911 in a rotary-motored monoplane than any other pilot in the United States I can only admire him for defending it so strongly, for its merits have been shown time and time again, but I fear that his arguments of late have been bordering very closely to narrowness, and he gives the impression that he is far from being open to conviction

While I have not had a great deal of experience in flying with a rotary motor, I have made a number of flights in the most successful type of American-manufactured biplane, which happened to be equipped with one I can truthfully state that I felt the gyroscope action whenever I made a turn with it, much more than I had ever felt it when using the stationary type of motor And I can vouch for it that every student whom I instructed on that machine last winter in California will say the same thing of it I am not foolish enough to ever think of knocking the rotary motor, for the wonderful records which have been made with it stand out as a glorious monument to its design I simply state that there is a gyroscopic action when it is used, and this is far from being negligible in practice

Control of the Mississippi

To the Editor of the SCIENTIFIC AMERICAN

In the December 7th number of the SCIENTIFIC AMERICAN there was published a letter by Mr N J Noble concerning the control of the floods of the Mississippi River Mr Noble suggests as a remedy "the construction of reservoirs in the upper courses and tributaries, in the case of the Mississippi the numerous tributaries of the Missouri in particular"

Possibly in the case of the Missouri Mr Noble's plan may be of some merit but the contrary most certainly appears to be the case with the Mississippi itself Close to the head waters of the Mississippi in northern Minnesota, at Leech, Winnibigoshish and Pokegama lakes the United States War Department has already constructed three large concrete dams, forming reservoirs many square miles in extent in the lakes and swamps through which the river passes These dams have been completed and in operation for several years quite a sufficient time to demonstrate their value in the control of floods, but the results obtained in that direction are very doubtful, so doubtful in fact that there has been serious complaint from people living on the lower lands along the river for at least three hundred miles below the dams, that their presence increases rather than decreases floods

One reason that a system of reservoirs does not control floods seems to be that the straw that breaks the camel's back, the extra water that causes the flood, comes on top of reservoirs already filled by a long wet season or by the annual spring freshet. It is not the unusual annual freshet that causes floods, but any unusual fall coming on top of this

This has been shown by the reports of experts who have investigated the influence of a forested watershed on stream flow as compared with a non-forested one The forest floor acts as an enormous reservoir, absorbing and retarding for a considerable period large amounts of water, and thereby regulating stream flow and lessening the volume of many small freshets The authorities usually agree, however, that the ultimate high-water mark attained by the stream is not lowered by the presence of the forest, for the excess water that causes the serious flood always comes on top of a forest floor already saturated, a reservoir already filled, the result is quite as much run off as though the forest floor or the reservoir did not exist.

Mr Noble suggests that by reference to our geographies we may learn that "certain characteristics and facts pertain to all of that large class of rivers of which the Mississippi is one, namely, that those rivers have their rise in hilly or mountainous countries" If he will turn to any good contour map of Minnesota, or of the United States, he may be surprised to learn that the Mississippi does not rise in a mountainous or hilly country, but instead rises and flows for miles through a country of very slight relief and with an absolute elevation of only about 1,600 feet above sea level The result is that the reservoirs overflow several thousand acres of low-lying land, which they convert into festering mosquito-breeding swamps in summer and impassable tangles of prostrate water-killed timber in winter The lakes converted into reservoirs, instead of being a "thing of beauty and a joy forever," as nature made them, have their natural shore lines spoiled and in many places made inaccessible and their waters polluted with green algae and pond scum as a result of the widely shifting level and the thousands of acres of now submerged and now exposed flowage, which is caused by manipulating the gates of the dams to control the flow of water

Perhaps the Mississippi can be controlled by a system of dams, but results so far obtained in Minnesota seem decidedly to point to the contrary H R FLINT,

Osakis, Minn

The Inventor and His Reward

To the Editor of the SCIENTIFIC AMERICAN

As an inventor I am gratified at the firm stand you have taken for the protection of the inventor's rights in the discussion of the patent bill now before Congress and you certainly have justice on your side Article I, Section 8, of the Constitution says (par 8) "The Congress shall have power to promote the progress of science and the useful arts by securing for limited times to authors and inventors the *exclusive* rights to their respective writings and discoveries"

The word "exclusive" would seem to be broad enough to cover every point at issue, and would certainly cover the fixing of price and sales conditions by the inventor "Exclusive" certainly implies a monoply, and nowhere in the Constitution is Congress given power to abridge this grant other than by limiting the time it may run, and I am satisfied that the Supreme Court will take this view of the matter, in case the proposed bill should be passed

The wisdom of the framers of the Constitution in recognizing the rights of authors and inventors is amply proved by the history of industry in this country

The present stupendous wealth and prosperity of this country is due solely to its inventors This seems a strong statement to make, but it is easy to prove its truth

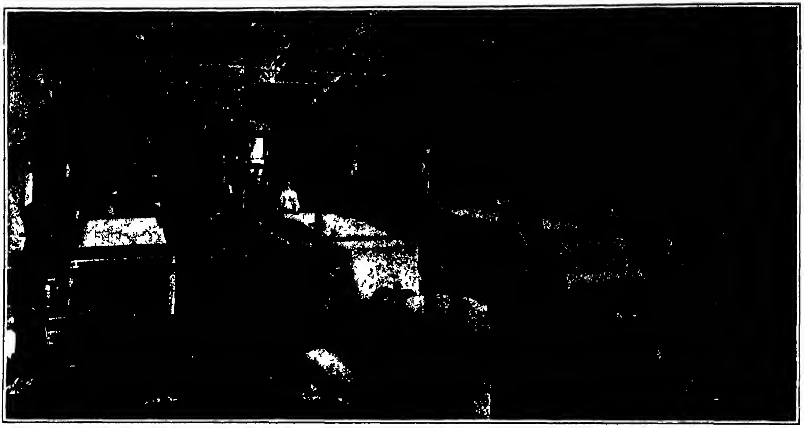
The vast resources have existed since prehistoric times, but their present utilization has been possible only through the work of the inventor The cotton gin made cotton a profitable crop the steamboat and the railroad made it possible to raise it in the interior and it has gone on increasing until this year Texas alone raised $300-000,000 of cotton The railroad, while first tried in England was first proposed by an American inventor and first brought to perfection here as a freight carrier The steamboat was distinctly American Agricultural machinery was the product of this country and without it the middle West would still be The Great American Desert" as it was once called Here intensive *farming* will not pay on account of scanty rainfall but extensive *farming* will, *and one man can* with the present labor-saving machinery farm as much as twenty men could by hand and do it better The Secretary of Agriculture estimates this year's farm products at nearly ten billion dollars How much would it have been without the American inventor? What per cent of this enormous sum goes to him for his inventions?

John Deere, who invented the modern plow, McCormick with the reaper Appleby with his twine binder, are dead their profits have long since ceased, but the country is still reaping the benefits Was the exclusive right to their inventions an injury? Goodyear struggled for years, in poverty and failure with splendid courage and hope, to make a useful product from the useless raw rubber His ultimate success and the right for seventeen years to control his invention was a small reward for his long struggle The Government could not give him back his time it could not return his youth, all it could do was to secure his rights for a few years Was this an injustice to the public? Of what account was his profit in the first years of the industry compared to the comforts and conveniences to which his invention gave birth? And his story is but one there are many others most of them obscure, who labored no less diligently to improve conditions and appliances of mankind, many like him confronted for years by poverty and bitter failure made still more bitter by the jeers of those they were striving to benefit

Is it any more than simple justice that they should be enabled to reap a monetary reward for the fruits of their labor? As you say, they have created something which did not previously exist and which would not have existed but for their efforts, and in which their right supersedes that of the public On the other hand the first years of the life of an inventor are the least profitable, and infringers frequently destroy what profit there is The case of the Wright brothers is pertinent They risked their lives in making flying a success and have been engaged in expensive litigation since the issue of their patents, to secure the rights and profits which were rightfully theirs.

Instead of detracting from the value and profits of an inventor it would *seem* more worthy for Congress to secure the inventor more fully in his constitutional rights

Omaha, Neb L. W SMITH



The spreader room of a rubber factory

The Making of a Pneumatic Automobile Tire

A Trip Through a Tire Factory

By E. R. Hall

CRUDE rubber never reaches the manufacturer clean. Before it can be converted into a tire it must be washed. First it is cut up into small pieces, put into large vats of warmed water and allowed to soak in order to soften it sufficiently to be broken down in the machines. By means of a cracker, a machine consisting of two rolls with projections on their surfaces shaped like little pyramids, the two rolls revolving with a differential, one going considerably faster than the other, and being adjustable so that they can work close together or with some distance between them, the rubber is broken down into a coarse spongy mass. Water flows on to the rubber during the process, bringing down sand, dirt, bark and the many other foreign materials which come mixed with the rubber. The rubber is put through this machine a number of times until it is worked into a uniform condition. Some of the rubbers, like the Ceylons and Paras, will sheet out into a coarse sheet by being put through this machine, others, like the majority of the African rubbers, will fall apart and come down in chunks and have to be fed into the machine with a shovel.

After the rubber is broken down sufficiently in the cracker, it is next put through a washing machine built like a cracker, except that the rolls are grooved or rifled so that their action is not so severe. Water constantly runs over this machine, and the rolls work very close together, so that the rubber is finely ground and run out into a thin and comparatively smooth sheet, allowing the water flowing between the rolls to take out practically all of the foreign matter that remains. Some types of rubber, such as Mangabeira, which have large quantities of sand in them, are washed in a special form of washing machine known as the beater washer—an endless, oval-shaped trough with a fast revolving paddle wheel. In this machine the rubber is submerged in water after being broken down in the cracker, and the sand is literally knocked out of it by the paddle wheel. The sand drops to the bottom of the machine, where it is drained off, while the rubber floats to the top to be gathered and then put through a regular washing machine for the final sheeting out.

Mounting the partially cured tire on a rim preparatory to final vulcanization in inflated form

Machine for cutting the fabric into bias strips.

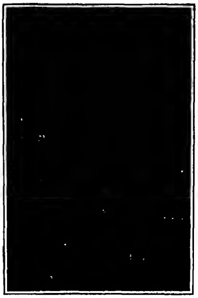
How the Rubber is Dried.

Before the rubber can be used in any articles of commercial value it must be thoroughly dried. Any moisture in the stock would turn to steam during the vulcanizing process and give rise to blisters or blow holes in the goods. There are two ways in which rubber is usually dried. The method mostly used and generally practised with all the better grades of gums, is to hang the washed strips on horizontal poles and space them in aisles, so that air may freely circulate around the surface of the rubber, the dry room being kept at a constant temperature. To dry the rubbers properly by this method takes from four to six weeks.

The other method is vacuum drying. Low grade rubbers which have a comparatively large percentage of resin in their composition cannot bear their own weight when hung on horizontal poles, but drop off. Hence these rubbers have to be dried in a peculiar manner. They are laid in trays which are placed into a large air-tight receptacle. Then the air is withdrawn and the interior heated by means of steam coils. Thus the water is evaporated from the rubber at a considerably lower temperature than that at which water boils under atmospheric pressure, and at such a low temperature, and in such a short time, that the rubber is not affected. By this process, these rubbers can be dried in a few hours.

Ingredients and Their Purpose.

After having been thoroughly dried, the rubber is ready to be mixed in proper proportions with the various ingredients, which give the desired quality for various products. In order that rubber shall vulcanize, it is necessary to mix with it a certain proportion of sulphur, vulcanizing, or curing as it is sometimes called, being merely the changing of a physical mixture of rubber and sulphur into a chemical



Applying the tread.

Arranging fabric on tire-building machine

The wrapping room of a pneumatic tire plant

compound of these ingredients, by the application of heat. Besides sulphur some of the more important ingredients used in compounding rubber are:

Zinc Oxide. This toughens the rubber and increases its wearing properties and tensile strength.

Barium Sulphate. This stiffens the rubber and adds weight, so reducing the cost.

Lithopone. This whitens the stock and makes it soft, and is used extensively in druggists' sundries.

Antimony Sulphide. This makes the stock red and is a preservative against oxidation.

Litharge. This has the same action as antimony sulphide but makes the stock black.

White Lead. This hastens the cure and is extensively used in gray and black stocks and is a good filler or weight adder.

Magnesia Oxide and Carbonate. These are used as fillers for white stocks.

Oxide of Iron. Used for coloring red and yellow stocks.

Lime (unslaked). This hastens vulcanization and chemically removes any water left in the rubber.

Whiting. This is used only as a cheap filler to increase quantity and lower cost.

Aluminium Silicate. This is used chiefly as a filler.

The various ingredients mixed with rubber are not put into the compounds merely to cheapen the product and to lower the grade of the material. While true of molded goods, rubber heels, bicycle grips, automobile bumpers, etc., it is not true of tires, packing, belting, etc. Ingredients are added in the case of tires

Finishing pneumatic automobile tires

Room where the compounded rubber is put through calenders.

to toughen the gum, increase its wearing qualities, to make it indestructible when subjected to heat, or to make it soft and yielding so that it can be forced into fabric, etc.

In the general process of manufacture the sheeted rubber is sent directly from the dry room to the compound room where the various ingredients are weighed out into proper proportions along with the rubber to make up a batch and placed in receptacles ready to be mixed. The batch is then sent into the mill room to be mixed into a uniform pasty mass, which is the characteristic uncured or so-called green rubber compound. The mixing is done in the mill, a very heavy machine resembling a cracker and a washer, except that it is much larger and heavier and that the rolls are perfectly smooth and run closer together. No water at all is used on the batch during the mixing.

After the batch is properly mixed it is cut off the rolls in sheets and rolled up and sent to the green stock storeroom. In this storeroom the compounded uncured gums are kept in different bins according to the nature of the compound and are there allowed to season a certain length of time, after which they are delivered to the various departments of the factory in which they are to be used.

Another form in which rubber is used is the so-called rubber cement. Rubber or any of its compounds are readily soluble in naphtha. In this process the compounds after being milled are macerated in specially constructed cement mills and there mixed with a certain proportion of naphtha which gives a thick solution

(Continued on page 51.)

Single cure process: The whole tire vulcanized after the tread has been applied.

Location of Gasoline Engine Troubles Made Easy

A Comprehensive Exposition of the Common Derangements That Interfere With Efficient Operation of All Types of Four-Cycle Internal Combustion Motors

Tables compiled by Victor W. Pagé, M.E., author of "The Modern Gasoline Automobile"

INSTRUCTIONS FOR USE

This chart has been prepared to outline in a simple manner the various troubles and derangements that interfere with efficient internal combustion engine action. While the form illustrated is a type used as a motor-car power plant, the parts and their functions are practically the same in all gas or gasoline engines of the four-cycle type, and the general instructions given apply just as well to all hydro-carbon engines, even if the parts differ in form materially. The essential components are clearly indicated in the part sectional drawing so they may be easily recognized. The various defects that may materialize are tabulated in a manner that makes for ready reference, and the various defective conditions are found opposite the part affected, and under a heading that denotes the main trouble in which the others are contributing causes. The various symptoms denoting the individual troubles outlined are given to facilitate their recognition in a positive manner.

Brief note is also made of the remedies for the restoration of the defective part or condition. It is apparent that a chart of this character is intended merely as a guide, and it is a compilation of practically all the known troubles that may materialize in gas-engine operation. While most of the defects outlined are common enough to warrant suspicion, they will never exist in an engine all at the same time, and it will be necessary to make a systematic search for such of these as exist.

To use the chart advantageously, it is necessary to know one main trouble easily recognized. For example, if the power plant is noisy look for the possible troubles under the head of Noisy Operation. If it lacks capacity, the derangement will undoubtedly be found under the head of Lost Power. It is assumed in all cases that the trouble exists in the power plant or its components, and not in the auxiliary members of the ignition, carburetion, lubrication, or cooling systems. The novice motorist and student will readily recognize the parts of the average engine by referring to the very completely outlined and clearly lettered sectional drawing in the illustration.

"SKIPPING" OR IRREGULAR OPERATION

PART AFFECTED.	NATURE OF TROUBLE.	SYMPTOMS AND EFFECTS.	REMEDY
Compression Relief Cock.	Leak in threads or spigot.	Dilutes mixture with air causes blowback.	Screw down tighter. Grind spigot to seat with emery
Spark Plug.	Leak in threads. Defective gasket. Cracked insulator. Points too near. Points covered with carbon. Too much air gap.	Dilutes mixture. Allows short circuit. No spark.	Screw down tighter. Replace with new. Set points 1-64" apart for magneto, 1-32" for battery spark.
Valve Chamber Cap.	Leak in threads. Defective gasket.	Dilutes mixture by allowing air to enter cylinder on suction stroke.	Previously given.
Combustion Chamber	Carbon deposits.	Preignition.	Scrape out.
Valve Head.	Warped or pitted. Loose on stem.	Dilutes charge with poor air or gas.	Previously given.
Valve stem.	Binding in guide. Sticking.	Irregular valve action.	Previously given.
Valve Seat.	Scored or warped. Cracked. Covered with scale. Dirt under valve.	Gas leak, poor mixture. Poor compression. Valve will not close.	" "
Induction Pipe.	Leak at joints. Crack or blowhole.	Mixture diluted with excess air	Stop all leaks.
Inlet Valve.	Closes too late. Opens too early	Blowback in carburetor	Time properly
Exhaust Valve.	Opens too late. Closes too early	Retention of burnt gas dilutes charge	Time properly
Valve Stem Guide.	Bent or carbonized.	Causes valve to stick.	Previously given.
Inlet Valve Stem Guide.	Worn, stem loose.	Air drawn in on suction thins gas.	Bush guide or use new member
Valve Spring.	Weakened or broken.	Irregular action.	Use new spring.
Valve Stem Clearance	Too little. Too much.	Valve will not shut. Valve opens late, closes early	Adjust gap .025" inlet, .008" exhaust.
Valve Spring Collar Key	Broken.	Releases spring.	Replace
Cam.	Worn cam contour. Loose on shaft. Out of time	Valve lift reduced. Does not lift valve. Valves operate at wrong time	Previously given.
Camshaft Bearing.	Looseness or wear	Valve timing altered. Valve lift decreased.	Replace.
Camshaft.	Twisted.	Valves out of time	Previously given.
Cam Fastening.	Worn or broken.	Valve action irregular	Replace with new
Valve Operating Plunger	Loose in guide	Alters valve timing	Replace with new
Valve Plunger Guide	Wear in bore. Loose on engine base	Alters valve timing	Replace or bush. Fasten securely
Timing Gears.	Not properly meshed. Loose on shaft.	Valves out of time. Valves do not operate	Remesh properly. Fasten to shaft.
Piston.	Walls scored.	Leakage of gas.	Smooth up if possible
Piston Head.	Carbon deposits. Crack or blowhole core	Causes premature ignition.	Previously given.
Piston Rings.	No spring. Loose in grooves. Worn or broken.	Leakage weakens suction.	" "
Cylinder Wall.	Scored by wristpin. Scored by lack of oil.	Gas leaks by. Poor suction	" "

LOST POWER AND OVERHEATING

PART AFFECTED.	NATURE OF TROUBLE.	SYMPTOMS AND EFFECTS.	REMEDY
Water Pipe Joint.	Loose.	Loss of water, heating.	Tighten bolts, replace gasket.
Spark Plug.	Leakage in threads, insulation, or packing.	Loss of power. Hissing caused by escaping gas.	Replace insulation if defective, screw down tighter
Compression Release Cock.	Leak in threads. Leak in fitting.	Loss of power. Whistling or hissing.	Tighten if loose. Grind fitting to new seating in body
Combustion Chamber.	Crack or blowhole. Roughness. Carbon deposits. Sharp edges.	Loss of compression. Pre-ignition.	Fill by welding. Smooth out roughness. Scrape out or dissolve carbon.
Valve Chamber Cap.	Leak in threads. Defective gasket.	Loss of compression. Hissing.	Remove. Apply pipe compound in threads and replace. Use new gasket or packing.
Valve Head.	Warped. Scored or pitted. Carbonized. Covered with scale. Loose on stem. (two-piece valves only)	Loss of compression.	True up in lathe. Grind to seat. Scrape off. Smooth with emery cloth. Tighten by riveting.
Valve Seat.	Warped or pitted. Covered with carbon. Foreign matter between valve and seat.	Loss of compression.	Use reseating reamer. Clean off and grind valve to seat.
Valve Stem.	Covered with scale. Bent. Binding in guide. Stuck in guide.	Valve does not close. Loss of compression.	Clean with emery cloth, straighten. True up and smooth off, free with kerosene.
Valve Stem Guide.	Burnt or rough. Loose in valve chamber	Valve may stick. Action irregular.	Clean out hole. Screw in tighter.
Valve Spring.	Weak or broken.	Valve does not close.	Replace with new.
Valve Operating Plunger.	Loose in guide. Too much clearance between valve stem.	Valve action poor. Lift insufficient.	Replace with new. Adjust screw closer
Valve Lift Adjusting Screw	Threads stripped. Too near valve. Too far from valve.	Poor valve action.	Replace with new. Adjust with proper reference to valve stem.
Valve Lift Cam.	Worn cam contour. Loose on shaft. Out of time.	Not enough valve lift. Will not lift valve. Valve opens at wrong time.	Replace with new. Replace pins or keys. Set to open properly
Camshaft.	Sprung or twisted.	Valves out of time.	Straighten.
Camshaft Bushing	Worn.	Not enough valve lift.	Replace.
Camshaft Drive Gear	Loose on shaft. Out of time. Worn or broken teeth.	Irregular valve action.	Fasten securely. Time properly. Replace with new
Cam Fastenings.	Worn or broken.	Valves out of time	Replace with new
Cylinder Wall.	Scored, gas leaks. Poor lubrication causes friction.	Poor compression. Overheating.	Grind out bore. Repair oiling system.
Piston.	Binds in cylinder. Walls scored. Worn out of round	Overheating. Poor compression.	Lap off excess metal. Replace with new
Piston Rings.	Loss of spring. Loose in grooves. Scored. Worn or broken. Slots in line.	Loss of compression. Gas blows by	Peen ring or replace. Fit new rings. Grind smooth. Replace. Turn slots apart.
	Carbon in grooves. Insufficient opening. Binding on cylinder	Overheating because of friction.	Remove deposits. File slot. Grind or lap to fit cylinder bore
Wristpin.	Loose scores cylinder	Loss of compression.	Fasten securely. Replace cylinder if groove is deep.
Crankshaft.	Scored or rough on journals. Sprung	Overheating because of friction.	Smooth up. Straighten.
Crank Bearings. Main Bearings.	Adjusted too tight. Defective oiling. Brasses burned.	Overheating because of friction.	Adjust freely, clean out oil holes and enlarge oil grooves.
Oil Sump.	Insufficient oil. Poor lubricant. Dirty oil.	Overheating.	Replenish supply. Use best oil. Wash out with kerosene, put in clean oil.
Water Space. Water Pipes.	Clogged with sediment or scale.	Overheating	Dissolve foreign matter and remove
Fan Belt.	Loose or broken.	Overheating.	Adjust or replace
Piston Head.	Cracked (core). Carbon deposits.	Loss of compression. Pre-ignition.	Weld by autogenous process. Scrape off carbon accumulations.

NOISY OPERATION OF POWER PLANT

PART AFFECTED.	NATURE OF TROUBLE.	CHARACTER OF NOISE.	REMEDY
Compression Release Cock.	Leakage.	Hissing.	Previously given.
Spark Plug.	Leakage	Hissing.	" "
Valve Chamber Cap.	Leakage.	Hiss or whistle.	" "
Combustion Chamber	Carbon deposits.	Knocking.	" "
Inlet Valve Seat.	Defects previously given.	Popping in carburetor	" "
Valve Head.	Loose on stem.	Clicking.	" "
Valve Stem. Valve Stem Guide.	Wear or looseness.	Rattle or clicking.	" "
Inlet Valve.	Closes too late. Opens too early.	Blowback in carburetor	" "
Valve Spring.	Weak or broken.	Blowback in carburetor.	" "
Cylinder Casting.	Retaining bolts loose. Piston strikes at upper end.	Sharp metallic knock.	Tighten bolts. Round edges of piston top.
Cylinder Wall.	Scored.	Hissing.	Previously given.
Valve Stem Clearance.	Too much. Too little (inlet valve)	Clicking. Blowback in carburetor.	" "
Valve Operating Plunger. Plunger Guide.	Looseness.	Rattle or clicking.	" "
Timing Gears.	Loose on fastenings. Worn teeth. Meshed too deeply	Metallic knock. Rattle. Grinding.	" "
Cylinder or Piston.	No oil or poor lubricant.	Grinding.	Repair oil system.
Cam	Loose on shaft. Worn contour	Metallic knock.	Previously given.
Camshaft Bearing	Looseness or wear.	Slight knock.	" "
Cam Fastening.	Looseness.	Clicking.	" "
Piston.	Binding in cylinder. Worn oval, causes side slap in cylinder.	Grinding or dull squeak. Dull hammering.	" "
Piston Head.	Carbon deposits.	Knocking.	" "
Piston Rings.	Defective oiling. Leakage. Binding in cylinder.	Squeaking. Hissing. Grinding.	" "
Wristpin.	Loose in piston. Worn.	Dull metallic knock.	Replace with new member.
Connecting Rod.	Wear in upper bushing. Wear at crankpin. Side play in piston.	Distinct knock.	Adjust or replace. Scrape and fit. Use longer wristpin bushing.
Crank Bearings.	Looseness. Excessive end play. Binding. Shaft too tight.	Metallic knock. Intermittent knock. Squeaking.	Refit bearings. Longer bushings needed. Insert shims to allow more play
Main Bearings.	Looseness. Defective lubrication.	Metallic knock. Squeaking.	Fit bearings closer to shaft. Clean out oil holes and grooves.
Connecting Rod Bolts. Main Bearing Bolts.	Loose.	Sharp knock.	Tighten.
Crankshaft.	Defective oiling.	Squeaking.	Previously given.
Engine Base	Loose on frame.	Sharp pounding.	Tighten bolts.
Lower Half Crankcase.	Bolts loose.	Knocking.	Tighten bolts.
Flywheel.	Loose on crankshaft.	Very sharp knock.	Tighten retention bolts or fit new keys.
Oil Sump.	Oil level too low. Poor lubricant.	Grinding and squeak in all bearings.	Replenish with best cylinder oil.
Valve Plunger Retention Stirrups.	Looseness.	Clicking.	Tighten nuts.
Fan.	Blade loose. Blade strikes casing.	Clicking or rattle.	Tighten. Bend back.
Fan Hub Bearings.	Broken ball.	Clicking.	Put in new ball.
Induction Pipe Joints.	Leakage.	Sharp whistle	Use new gasket.
Exhaust Pipe Joints.	Leakage	Sharp hissing.	Tighten or use new gasket.
Crankcase Packing	Leakage.	Blowing sound.	Use new packing. Tighten bolts.
Water Pipe.	Leaks. Loss of water. Clogged with sediment.	Pounding because engine heats.	Previously given.
Water Jacket.	Clogged with sediment. Walls covered with scale	Knocking because engine heats.	Dissolve scale and flush out water space with water under pressure.

The Riviera Gateway between France and Italy (Menton Vintimiglia)

Europe's Good Roads

What They Mean to Road Users

By Francis Miltoun

This article is a review of the best road engineering practice of Europe. While there are just as good roads in the United States to-day as in France, for example, our mileage of good roads is hopelessly outdistanced by the corresponding mileage of European countries that cannot compare with us in population or in national wealth. As a matter of business itself, the good roads question is one of the biggest on the economic horizon to-day. Americans should know how Europe is endeavoring to solve that problem. This article will tell them.—EDITOR.

Broad flat flagstones mark the through routes passing through Italian towns.

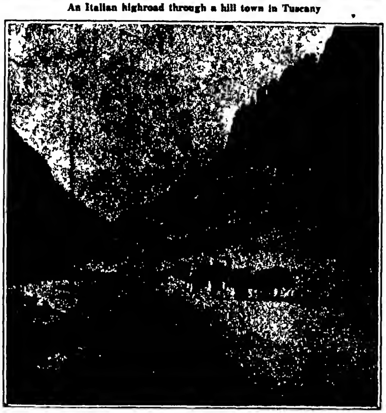
IT is no retrograde movement that proclaims comfortable travel by road as one of those twentieth century blessings which is our due. It is an axiom that the speedy railway development of the United States worked to the detriment and discouragement of scientific road building. Old Europe suffered under no such handicap. Roads, more or less perceptible were there. Take the case of France as the conclusive, concrete example because France has the greatest continuity and excellence of good roads to-day—since the Roman invasion, a fact which is evinced by one of the celebrated *bornes milliaires*—the mile stones of the Roman era—which sits beside a tree-bordered Route Nationale not a stone's throw from where these lines are written. The roads of Gaul were planned on grand lines: their great scope even at this late day cannot be denied and proves that they are a tangible expression of planning for the future. French roads of to-day follow these same general lines. It is thus that Europe got her start. What is more remarkable, France through the application of the same nation wide governmental and centralized roads control system, has endowed Algeria (in something less than three quarters of a century) with highways as good as those of the mainland itself. It is not solely then because a country is new that its roads should have been ignored or neglected, not even on the insistence of big business, for as a matter of business itself the good roads question is one of the biggest on the economic horizon to-day.

The Influence of the Romans.

All this has for long been recognized in France and her famous *Ecole des Ponts et Chaussées* (which gave the inspiration for the establishing of the highway engineering chair at Columbia University) turns out its road engineers all trained to the same methods. This of itself produces a uniformity of design and treatment which has done much toward putting French roads into the enviable class in which they stand. If a further endorsement of this paternalism were needed it can only be added that the recently founded department of the government, the *Office National de Tourisme*, is working hand in hand with the road building authorities for the provision of the funds necessary to build new roads which shall open up many hitherto closed regions to a rapidly increasing tourist traffic. This is not by any means an idle catering to the classes of leisure, the spenders; the development of a hitherto inaccessible region to tourists means that all the allied interests which may previously have languished will at least become producers able to furnish a more comfortable livelihood for many a mountain community which hitherto eked out but a perilous existence or emigrated to the shores of the Seven Seas. It was this combined effort of two friendly governmental departments which brought into being the magnificent *Route des Alpes* from Lake Leman to the Mediterranean—five hundred miles of superb mountain roadway through the Alps of Savoy and Dauphiny—and which in a like manner is achieving the *Route des Pyrénées* from the Bay of Biscay to the Mediterranean. The famous *Corniche d'Or* of the Esterels, too, a magnificent forty kilometer stretch of shelf like, cliffside Mediterranean, bordering the Riviera, just before Cannes, owes its existence to a like initiative. Formerly it was but a coast guard's trail, to-day it is the most beautifully disposed and most remarkably engineered roadway extant.

On a Swiss mountain road.

An Italian highroad through a hill town in Tuscany



The French have built fine roads in Algeria. This is the Col de Sfa, the gateway of the Garden of Allah (Biskra).

It is remarkable the wide interest that the road question has for all classes in Europe and it is this unity of purpose that builds on the network legacy left by the Romans. Since that time, and that of the Henris and the Louis, to whom were due much of the elements of beauty that compose the French road system to-day particularly with respect to tree planting alongside, and since the later day of the military road making genius of Napoleon much has been undertaken in the way of refinement which has produced, if not an actual money return, at least a prosperity which would otherwise have been unknown.

European and American Roads Compared.

To be just there are as good roads in the United States to-day as in France in top-dressing, in comport with the needs of the new locomotion, according to any one of the four or five methods commonly made use of in America results are superior even to anything yet achieved in Europe. That these "surface roads" are as durable is a question not for discussion here. The rock metalled, water bound macadam of Britain, precursor of the Frenchman, Trésaguet, the *pflaster* of Germany or the *pavé* of Belgium at their best are certainly no better to the eye, nor in actual practice when seated on luxurious upholstery and rolling on rubber tires, than much that may be seen in short lengths in some States of the Union.

Little has been achieved in Europe in the redressing of existing roadways with tar, asphalt, cement or any form of bitulithic carpeting which is known so favorably, in one form or another, in America, and which in most cases has been found superior to purely water-bound road-surfacing. In France, particularly, where the thing has been tried, pitiful results have accrued, notably on certain stretches along the Riviera, that battery of Mediterranean coast towns which has become the playground of princes, American millionaires and some others.

Brick is found on some roads of Holland, but it dates from before the automobile era, before even that famous pavement of Terre Haute, Indiana, owning already to some twenty years and still good. Great claims of durability are made for brick, and if these two examples have any weight, the thing would seem to be worth something.

In France there is a famous forty kilometer stretch of *Route National* in the south, near Marseilles, just after leaving Avignon and Arles on the road to the Riviera, straight as an arrow, flat as a billiard table and smooth as marble, with a road of wind-break cypresses on the north, which in the writer's opinion is the very nearly ideal roadway. French

National, Departmental and Communal roads, as a class, are the best in the world. Here and there, it is true, they are showing signs of wear, but the system of upkeep is such that they seldom degenerate into downright bad. From the Channel Ports to Paris there are superb bits of tree-lined roadway, wide well drained and marvelously engineered, the typical *Routes Nationales*, which have set the pace for all other main highways of the world. South in Poitou and through the Limousin are long silent stretches nearly as good. In the Pyrénées are found superb mountain highways on the French slope and something unspeakable on the Spanish versant, with the result that Alphonse XIII, Europe's automobiling monarch, does most of his road travel in France. In the French Alps are the finest mountain roads in Europe, far and away ahead of those of Switzerland on all counts. Many of them were due to the genius of Napoleon and his military road builders, and if their main purpose in times past was strategic, to-day they are certainly essentially practical. The Col du Mont Cenis, the Col de Mont Genevre, the Lanteret and the giant Gallbier (the highest carriage road in Europe save the Stelvio) at an elevation of a mile and two thirds, are the best of their kind, though commonly one thinks of the mountain republic of Switzerland or Italy or Austria when mountain roads are mentioned.

The Mountain Roads of Austria.

The mountain roads of Austria are a close second, particularly when it comes to considering them from the point of view of the automobile. The country is trying hard to get some of the thirty millions which is claimed to be left abroad each year by foreign automobilists in Europe, and it has accordingly put its mountain roads in shape and opened up many new ones within the last decade, until to-day there is a continuous round of fifteen hundred miles at no less an elevation than three thousand feet, with many of the passes, like that of the Stelvio well above six thousand. Autophobic Switzerland is a big loser with its circumscribed system of cantonal option, resulting that it is but a bridge for the "fast traffic" between Paris and the Italian Lakes instead of being the touring ground that it was in the eyes of a former generation. One enters Italy over the Saint Gothard or the Simplon or Tyrol over Arlberg, but a bare three hundred miles of cross country is all that is left to Switzerland on the main touring route, the valleys and many of the interior roads being given over exclusively to carriage and mail coach, horse-drawn traffic of the days of Mark Twain.

Italy has a nationalized roads system so has Belgium, Austria and most of the German Confederation. The first three meet the situation but partially, organization and control being decidedly inferior to that in France. Italy's *Strade di Grandi Communicazione* are sometimes good, more often bad, and around Naples, Rome and Florence and north toward the Italian Lakes *via* Milan they are too bad for words, having arrived at this disgraceful stage through sheer neglect or inattention rather than through any fault in the system of road building in itself. Level crossings, with great well sweep gates, always shut, abound—there are fifty of them between Vintimiglia and Spezia on the Italian Riviera, the Poor Man's Riviera, so-called to distinguish it from that around Nice and Monte Carlo.

To sum up and bring it home, there is nothing worse in Europe than stretches within half a hundred miles of Manhattan, and nothing quite so good, even in the Bois de Boulogne, as some of the hard-surfaced ribbon roads leading out into the Jersey Hills. Roads in Europe are an economic factor of life and not a fad, however. Recently we read of an army division in the Balkans which made a hundred miles with all its train in a little more than a week, and that truly is going some, even on a first class open road, and military strategic roads are invariably good roads, though they may not be so numerous or have the extent of those mundane thoroughfares which lead merely from town to town. Neither is the farmer abroad taxed in strength, patience, time or purse. In France he is assured a road grade which will enable his beast of burden to pull three tons at a walking gait without aid, an echo of a formula first promulgated by Napoleon—no grades upon which a mountain battery might not gallop at ten kilometers an hour. It is this general, foreordained, inter locking engineering scheme that puts the continental European roads from the Pyrénées to the Carpathians in the high class which they occupy as strategic military roads unexcelled anywhere. Their "feeders" are of the same general excellence resulting in a benefit to all sorts and conditions of society not automobilists alone,

National road through the forest of Fontainebleau.

The Gorges d'Ollioulles in the Maritime Alps.

though, to be fair it was the advent of the rubber tire that has caused the wide revival in the question of road travel throughout the civilized world.

England's Parochial System.

England's parochial system of road control is the chief of the difficulties which road users are experiencing in the tight little isle, and have experienced for long, though it is hoped that the newly founded Road Board (whose secretary, Mr. Rees Jeffreys, was recently in the United States to learn what he might with regard to the fining down of automobile roads, particularly with respect to surfacing) will remedy all this just as soon as it becomes really national in its functions and not merely advisory leaving the county and parish authorities to do pretty much as they please. Towns and villages in England are often so close together that a highway is frequently one long main street—narrow and twisting at that and the famous Bath Road of history, for a length not appreciably more than a hundred miles, is under control of a dozen different road builders, each with methods of his own. Results are variable. One length of but a few miles, entering London from the west, is under the *régime* of three different urban councils of greater London. In France, or in any of the continental countries where the national system prevails, this could not be.

Uniform control in France makes a national road of the main street of many a populous town and as such it is under the direct supervision of the national road building authorities and as goes without saying, is kept up to national standards often having a stone kilometer mark set into the facade of the town hall or a Gothic church which may date from the middle ages. It is as if the King's Highway, or *Route Royale* from which the French *Route Nationale* of to-day has descended, were ambling along in the open plain of La Beauce, the granary of France where, for miles on end there are nothing but waving wheat fields on either side no hedgerows, as in England, no paving blocks as in Belgium and no snake-rail fences as in America—nothing but straight white, smooth surfaced road way along which the automobilist may make what speed he may so long as he doesn't hit anything.

Speed on European Roads.

Speed limits in continental Europe save for local option in the *agglomerations* the populated centers are in general tacitly liberal only in Britain and in Switzerland are they intolerable if one excepts the ludicrous frequency of the posting of the word *verboten* in Germany particularly in the Rhine Provinces of the Confederation.

European roads by no means cost as much as in America wages are lower to begin with and the budget is spread thin. France's ideal centralized system costs but 30,000,000 francs a year and the first classification of *Routes Nationales* little more than four thousand dollars a kilometer, with certain classes of local roads falling as low as four hundred. It is significant that road markings form as much a part of the European nationalized road systems as roadmaking. Great head stone like kilometer stones stare out at every five eighths of a mile and blue and white cast iron signboards are at *every* cross-road. In America we have depended largely upon private initiative to give us road directions with it must be confessed equivocal results, even admitting in the first instance that the intent was good.

German and Austrian roads as a whole are excellent in their main lines of communication and the mountain roads of the latter (which also has a National Touring Office which is fathering a pet project to make for the Alps of Tyrol and the Dolomites that which the automobile tourist fails to find in Switzerland) copied after the French formula run them a close second and are even more spectacular in that they frequently pass through long stretches of wildly savage country less thickly populated than Dauphiny and Savoy in old France.

Certain German roads are under particularly stringent road regulations and local taxes for upkeep and these bear on the stranger and the native alike particularly in certain localities in Wurtemburg and Bavaria but it is all in the line of progress and is therefore commendable. In the Black Forest and along the Rhine German roads reach their apogee and are in no way inferior to those of France which indeed so far as those of Alsace and Lorraine are concerned are allied to the French tradition of engineering if not of upkeep.

The frontier customs control stations of Continental Europe play a well defined part in the policing of

(Concluded on page 58.)

Will the Automobile Be Driven by Kerosene?

Problem of the Decreasing Supply of Gasoline and the Increasing Number of Internal Combustion Engines

By H. A. Morris

With 700 000 automobiles and motor trucks now in use as compared with less than 500 000 in 1911 and with tractors, motor boats, motorcycles and other gasoline burning engines increasing equally rapidly, it is interesting to note that the supply of high grade gasoline is decreasing. In fact there would have been a shortage in 1911 had it not been for the rapid development of the natural gas condensing process. This is the situation which has brought about the rise in the retail price of gasoline from 1[illegible] to 15 cents at retail and as low as 10 cents at wholesale a year ago to the present figures of 22 to 25 retail and 10 cents wholesale.

Considering too that the present season will boost the number of motor cars in use from the number mentioned to at least 850 000 while plans for 1911 show a production which will put the total beyond the million mark early this spring it really is a very grave situation, for with a falling supply of fuel there is a natural increase in its use of over 30 per cent. In 1911 the crude oil production increased but 3.5 per cent. Of this less than 10 per cent was classified as gasoline and naphtha while an additional 15 per cent was kerosene. The former totaled but 20 000 000 barrels while the kerosene added to these figures would give a total of 117 000 000 barrels.

This situation and these figures would seem to point the way out of the present dilemma, namely, the use of kerosene either as such with gasoline simply for a starting medium or mixed with the lighter fuels to make a compound which would be light and volatile enough to make starting, previously the great trouble, easy and simple.

Either one will necessitate new vaporization methods and different vaporizing devices. It will be interesting to note what has been done in this line. It will also be helpful to know what has been done with this and other heavier fuels in stationary engine practice, for good results there point out the way for future motor car success. In an extensive table published by the National Electric Light Association 29 users reported 1 oil engine each and 8, 2 each, making a total of 45 engines in 37 plants. The oil varied from 10 to 40 deg. Baumé specific gravity with the average at 28.5. The British thermal units in the fuel varied from 18 000 to 19 000, 20 showing 19 000 or more. Oil cost varied from 1.77 cents a gallon to 4 cents, 31 averaging 2.60 cents. Fuel cost a kilowatt hour for 17 varied from 0.180 to 0.501 cent and averaged 0.314 cent. Cost of horse power hour for 6 others varied from 0.181 to 0.778 cent and averaged 0.333. The total costs, including lubrication, waste and other supplies, also attendance, varied from 0.452 cent to 1.110 cent a kilowatt hour for 13 and averaged 0.708. The same on a horse power hour basis varied for 4 from 0.641 cent to 1.111 cents and averaged 0.910 cent. The power a unit varied from 75 up to 500.

This shows that heavy oils of one tenth the present cost of gasoline may be used with economy, no trouble and marked success in stationary engines. It remains only for motor car and gasoline engine builders to produce devices which will allow of using this same abundant fuel for these motors. In California stationary engine practice has been adapted to many automobiles by the simple addition of a pump, with piping and a tank, so as to spray water into the vaporizing chamber simultaneously with the admission of distillate, which is plentiful and costs about 2 cents a gallon. When this is done, the water furnishing additional oxygen for vaporization, bringing about more complete vaporization, preventing carbon deposits, softening down the explosions by producing a slower burning effect, and preventing pre-ignition, the usual cooling system is modified by the use of gaskets in the pipe connections, so that the cylinders and other parts will be kept slightly hotter (90 degrees is given as the most satisfactory figure).

In some fuel tests conducted about a year ago at the Automobile Club of America's laboratory in New York city on a standard four-cylinder automobile engine the power development on gasoline exceeded that of kerosene at 625 revolutions per minute by only 1 horse-power equal to 6.5 per cent, at 925 revolutions per minute by 1¾ horse-power equal to 8.1 per cent and at 1,210 revolutions per minute by 5.3 horse-power equal to 26.3 per cent. These tests were made without change of carburetor or any other change in the engine and would seem to show the necessity for a special vaporizing device for heavy fuels at the higher speeds where the difference shows the greatest.

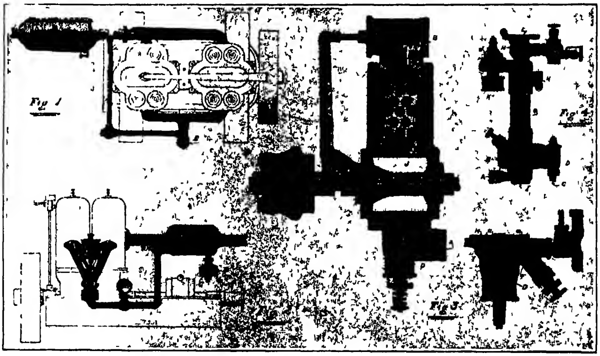
In the annual agricultural motor trials at the Winnipeg Fair, a class, increased to two classes in 1912 on account of heightened interest, is set aside for kerosene burning engines. From the 1912 results, taking engines of equal size and, where possible, of the same make, kerosene showed to advantage in nearly every direction. Thus the fuel cost of plowing an acre was lowered from 49.725 cents for 12 gasoline engines, with 64.9 as the highest and 37.3 as the lowest figure to 40.027 cents for 7 kerosene burners. The highest of the latter was 59.9 and the lowest 33.7. If this single very high figure had been eliminated in the average, the other 6 would have given 45.93 as a result. The number of horse-power-hours from a dollar's worth of fuel (the respective costs were 14½ cents for kerosene 19½ cents for gasoline as compared with 12 and 20 cents in 1912) was 73.42 using kerosene and 55.90 on gasoline. This shows to the advantage of kerosene by 31.3 per cent. In 1912, due to the difference in price, this same advantage in four selected classes was 64.2, 76.5, 42.5 and 50.4 per cent. In 1911 the figures were 27.5, 25.2, 10.9 and 74.3 per cent.

This shows that by using the fuels of lower specific gravity, commonly called heavier fuels because they weigh more, superior economy may be obtained varying from 11 to 75 per cent. Taking an average at 50, this means that with a proper vaporizing device for the heavy fuel, the owner of an automobile who got 70 miles for a dollar when burning gasoline, could change to kerosene and get 105 miles for a dollar. These figures reversed show that the cost a mile of this automobile for fuel alone would be nine tenths of a cent (0.9 cent) for kerosene as compared with 1.4 cents for gasoline.

In the main, the vaporization of kerosene is brought about by two things, a fine division of the liquid as it enters and the addition of a large amount of heat. It is preferable, experimenters tell us, to convert the chemical state, making the liquid into a fixed or permanent gas, but not all of the available vaporizers do this. The addition of the heat is usually by means of exhaust gases or jacket water or both, in many cases, the vaporizing device is actually placed in the muffler where it gets all the heat out of the exhaust gases before they are rejected into the air.

Some idea of the amount of heat necessary may be gained from the simple statement that good results cannot be obtained below 250 deg. Cent. (482 deg. Fahr.) and the best are produced at 300 deg. Cent. (572 deg. Fahr.). Two other considerations enter into the construction of the kerosene vaporizing device according to the results of the greatest experimenters, namely, accurate control of the fuel, and storage space or a device which produces flexibility. As to the former, the amount of liquid is so small as compared with the large volume of air that the latter or the gas produced must be controlled to give close and dependable results. As to the latter, starting and stopping in traffic call for a quick reduction or a storage place for gas produced in one case, and a quick acceleration of the rate of production or a storage space already filled to give the same result in the other.

Generally speaking, the devices abroad which have been successful on alcohol, benzol and other heavy fuels do very well on kerosene. Among these may be mentioned the Butler (English), Southey (English), Martha (French), Banki (Austrian), Brouhot (French), Capitaine (Italian), Longuemare (French), Merienfelde (German), Richard (French), Japy (French), Sleipner, Deutz & Koerting (German) and others, one of which is the better known Diesel engine. In may be interesting to compare the economy of the last named with a new device for using kerosene on an automobile motor brought out in England by an Italian engineer, G. Christianapolo, and called after him the G. C. This is inclosed in a muffler, so that all of the exhaust heat is used.



Kerosene and heavy oil fuel possibilities.

Fig. 1—Plan view of a four-cylinder automobile engine with universal oil converter attached. B, converter into which the exhaust gases pass in a straight flow. I, electrical admission device which governs amount of heat used in converting fuel to a gas and controls the admission of gas to cylinders.

Fig. 2—Side view of universal kerosene converter attached to a two-cylinder marine engine, where it takes the place of both carburetor and muffler. A, the converter with float at B and spray nozzle lever at C. The amount of gas and its passage is controlled by means of the lever I. This outfit is arranged for gasoline starting through the usual carburetor float chamber at G.

Fig. 3—Section through Davis (English) kerosene vaporiser acting in conjunction with a governor to give automatic control of the automobile engine. A, air inlet port. B, gas outflow port to the cylinders. C, control poppet valve. D, dashpot covering valve action. E, float chamber. F, kerosene jet. G, nozzle. H, pin to prevent the valve from turning. J, fan to break up mixture of kerosene gas and air. I, exhaust heated vaporizer for the now well diffused mixture. K, shaft driven from the motor.

Fig. 4—Sectional drawing of the Holley kerosene carbureter showing constructional features. The fuel enters at C, passing needle valve D and enters float chamber B, which is heated by exhaust gases entering at H and leaving at A. The primary air supply enters at the base at I, draws the fuel out of the spray nozzle E into vaporizing chamber F. G shows heated gas passage. Auxiliary air enters through valve J, which is prevented from fluttering by dashpot K. The completely mixed gas passes through valve M to the cylinder by the opening L. Simple mixing valve N is provided for gasoline used at starting.

(Concluded on page 51.)

Clever Devices that Help Motorists

European Inventions That Meet Real Needs

IT must be stated emphatically here that the technical refinements and auxiliaries to be described were not caused by any distrust in the ability of the cars to surmount the mountain difficulties, but by a desire to save time, trouble and possible penalties during the tour

As usual in races and reliability trials, the lubricating apparatus received the most careful attention. Almost every entrant had a little trick of his own by means of which he could increase his available oil supply, or accelerate the flow of lubricant to the parts where it was needed. Brakes and gasoline tanks also received due attention, priming apparatus and a host of unique improvements were invented and attached by the drivers themselves.

An English car, for instance, had a special rear spring suspension, shown in Fig. 1 The lowest of the horizontal leaves is fully five feet long and rotates in the center on a fixed pivot, as well as being fastened to a hinged support on the chassis frame. This construction is productive of extremely easy riding owing to the great length of the spring

In an Austrian car, shown in Fig 2, the manner of attaching the two spare wheels is unusual. The chassis frame carries a right angled iron pipe, threaded at the free end, upon which the wheels are slipped and retained by the cup *B* and the nut *S* The nut is fitted with a short handle, facilitating quick removal of the wheels. The brake adjusting device, shown in the same illustration, is the acme of simplicity, it consists of nothing but a double-threaded spindle inserted in the brake rod. To keep continuous watch over the motor a small electric lamp *L* is affixed to the dash board directly behind the engine, the whole being visible through the glass window *S* in the dashboard

An Italian car sported a queer looking radiator cap shaped like a rounded cone (Fig. 3), for the double purpose of condensing the steam rising from the radiator and preventing hot water from being carried away with the steam

Three emergency tanks were carried by a French car, illustrated in Fig 4 *B* represents the gasoline tank, *W* the extra water reservoir and *O* the emergency oil tank. The gasoline tank is of great capacity and is filled through the top of the back of front seat

The most novel, interesting and important device however, was seen on an Austrian car, shown in Figs. 6 and 7 While the arrangement of the emergency gasoline tank under the front seat is common practice, the installation of an air filter on the dashboard is a step that will be watched by every automobile manufacturer Dirt and dust carried into the carbureter through the air ports, are responsible for a large part of all the carbureter troubles and any scheme tending to eliminate this difficulty must needs command attention The filter is pictured in Fig 6, where *W* stands for the dashboard, *R* for the pipe leading to the carbureter, *S* for the permanent sieve and *T* for the easily removable linen filter, held in place by a brass ring The chief value of the device lies in the accessibility of the filter, and its removable linen sieve, which when clogged up can be replaced by a new clean one in a moment without stopping the car or the motor

One of the big German cars, outlined in Fig 5 evidently took no chances in being caught without a sufficient supply of gasoline The carbureter of this machine was of such a construction as to render the use of gasoline of different specific gravities unsatisfactory and in order to obviate this difficulty a plentiful supply of the sort of gasoline best suited to the carbureter was carried along sufficient for the entire trip The net weight of this extra supply was more than 600 pounds. *B* and *C* are pressure tanks, while *A* supplies the carbureter by gravity feed.

Fig 8 gives the arrangement of one of the many clever oil accelerators used on the tour The pump *P* forces air into *H* whence it escapes through either *A* or *B* according to the position of the two-way cocks *A* leads to the oil tank, *B* to the water reservoir The oil is not forced directly from the tank into the motor but rises first in the pipe *R* falling through a filter and the pipe *O* into the motor In Fig 8a is shown how the compressed air from the pump *P*, going through

(Continued on page 48)

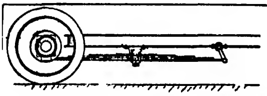


FIG. 1—A special rear spring suspension productive of extremely easy riding owing to the great length of spring

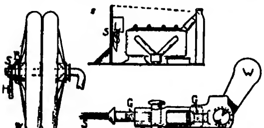

FIG. 2.—A novel way of attaching the two spare wheels.

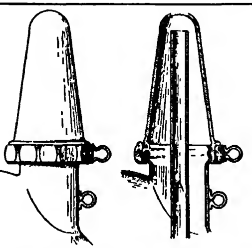

FIG 3 —This queer looking radiator cap serves the double purpose of condensing the steam rising from the radiator and preventing hot water from being carried away with the steam

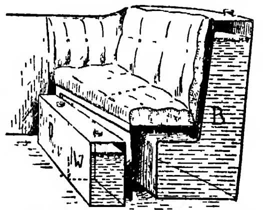

FIG 4 Three emergency tanks, of which *B* represents the gasoline tank, *W* the extra water reservoir and *O* the emergency oil tank The gasoline tank of great capacity is filled through the top of the back of the front seat

"Unpunishable infractions of the rules and regulations" one is inclined to call the little technical tricks and the refinements with which the participants in one of Europe's recent reliability runs for automobiles equipped their cars Although the aim of the tour was not to test and develop freak accessories for use on motor cars, the tourists felt the need of a little assistance in crossing the Alps during a contest Consequently they racked their brains for ways and means to increase the power, fuel capacity and lubricating facilities without transgressing the letter of the contest rules The following article, condensed from the Allgemeine Automobil Zeitung, succinctly describes the clever devices invented for the occasion —EDITOR.

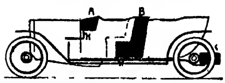

FIG. 5.—A big German car that could not operate with gasoline of different specific gravities. Sufficient fuel (600 pounds) for the entire trip was carried in pressure tanks *B* and *C* while the tank *A* supplied the carbureter by gravity feed.

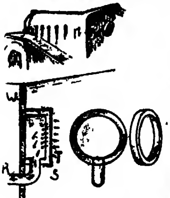
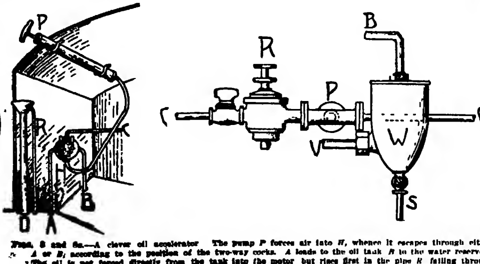


FIGS. 6 and 7.—*W* is the dashboard, *R* the pipe leading to the carbureter *S* the permanent metal sieve, and *T* the removable linen filter, held by a brass ring This air filter on the dashboard prevents dirt and dust from being carried into the carbureter through the air ports



FIGS. 8 and 8a.—A clever oil accelerator The pump *P* forces air into *H*, whence it escapes through either *A* or *B*, according to the position of the two-way cocks. *A* leads to the oil tank *B* to the water reservoir The oil is not forced directly from the tank into the motor but rises first in the pipe *R* falling through a filter and the pipe *O* into the motor Fig. 8a shows how the compressed air from the pump *P* passes through the reducing valve *R* to the fuel tank, forcing gasoline into the separator *W* where it is freed from water, and then through *V* to the carbureter

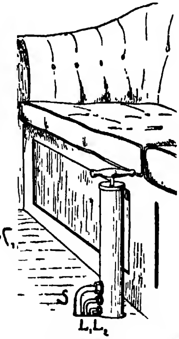


FIG 9—Another oil accelerator The pump is here located between the two front seats with three pipes *S* for suction from the oil tank L_1 for connection with the motor L_2 for the connection with the brakes

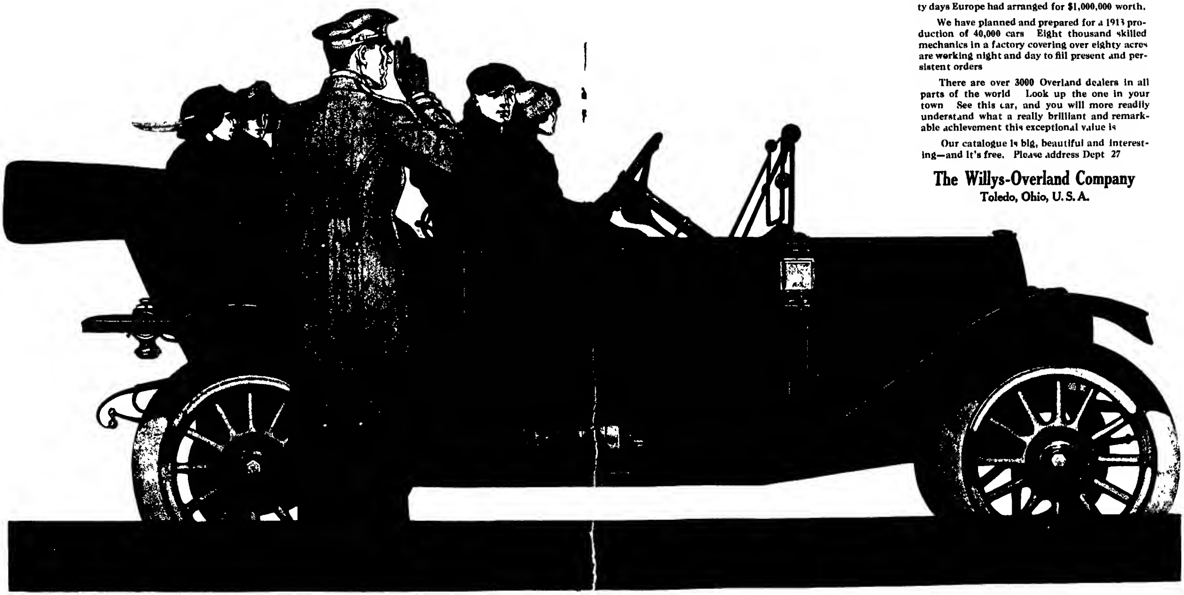
WE are, and have been, over 3000 cars behind immediate shipping orders ever since last August—when this model was first introduced Dealers contracted for 39,000 cars before we made a public announcement, one dealer alone took 4000, in thirty days Europe had arranged for $1,000,000 worth.

We have planned and prepared for a 1913 production of 40,000 cars Eight thousand skilled mechanics in a factory covering over eighty acres are working night and day to fill present and persistent orders

There are over 3000 Overland dealers in all parts of the world Look up the one in your town See this car, and you will more readily understand what a really brilliant and remarkable achievement this exceptional value is

Our catalogue is big, beautiful and interesting—and it's free. Please address Dept 27

The Willys-Overland Company
Toledo, Ohio, U.S.A.



the reducing valve *R* to the fuel tank, forces gasoline into the separator *W*, where it is freed from water, and then through *V* to the carbureter

Somewhat similar is the construction shown in Fig. 9. The pump is here located between the two front seats, with three pipes *S* for suction from the oil tank, L_1 leads to the motor, and L_2 to the brakes.

A priming device which was on nearly all the cars is shown in Fig 10 It consists of nothing more than a wire protruding through the radiator and attached at the other end to an angular lever *K* is the carbureter, *S* the float stem, *H* the lever, and *D* the wire.

More ingenious is the device shown in Fig. 11, which one of the drivers employed to obtain quick adjustment of the fan belt drive, without being compelled to stop the car—the run being a non-stop contest over mountain roads. Z_1 and Z_2 are actuated by the rod *W*. *H* is firmly fastened to the sector Z_3 and carries the shaft of the rotating fan, *R* is the belt. The rod *W* is controlled by a lever on the dashboard.

Still another clever device was used by a German car, and is illustrated in Fig. 12. It consists of a wind shield having a narrow slit in the glass. The arrangement guarantees a clear view ahead even if heavy rain and mud cover the glass. Inclining the shield more or less allows each driver to adjust the height of the slit to his own requirements, by means of the usual device, shown in Fig 13.

The last two illustrations show a time-saving device, which is not unknown in this country, in connection with the easier handling of touring maps. By means of rollers and a small frame with a glass front it is possible to keep the map in full view and yet safe from being blown out of one's hand, while the entire plate and holder can be folded under the cowl dash out of the way when not in use Special ribbon like maps are used in this device

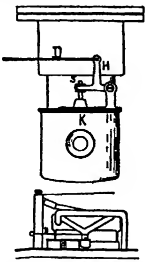


Fig. 10.—A priming device, consisting of a wire protruding through the radiator and attached at the other end to an angular lever *K* is the carbureter, *S* the float stem, *H* the lever and *D* the wire.

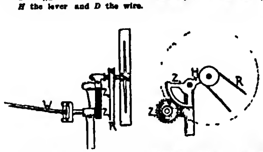

Fig. 11.—A device to obtain quick adjustment of the fan belt drive without being compelled to stop the car Z_1 and Z_2 are actuated by the rod *W* *H* is firmly fastened to the sector Z_3 and carries the shaft of the rotating fan, *R* is a belt. The rod *W* is controlled by a lever on the dashboard

Fig. 12.—A wind shield having a narrow slit in the glass thus guaranteeing a clear view ahead, even if heavy rain and mud should obscure the glass.

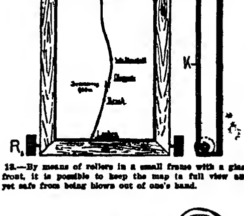

Fig. 13.—By means of rollers in a small frame with a glass front, it is possible to keep the map in full view and yet safe from being blown out of one's hand.

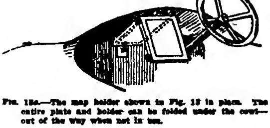

Fig. 13a.—The map holder shown in Fig. 13 in place. The entire plate and holder can be folded under the cowl—out of the way when not in use.

The Carob Bean Tree

THE carob bean is the commercial name for the ripe pods or fruit of a tree called botanically *Ceratonia siliqua* Linn of the pea family of plants. The fruit of this tree is variously known as carob, carob bean, algaroba algarroba, karoub, caroubier, locust, sweet bread, sugar pod, and St John's bread It is supposed that these seed pods are the locust and wild honey which St John found in the wilderness hence the derivation of the common name of St John's bread. The "husks" on which the prodigal son of scripture subsisted were the dry pods of the carob bean The tree is a native of the European, African and Asiatic countries bordering on the Mediterranean Sea, but it has now become naturalized in practically all localities in which oranges are grown It is a beautiful evergreen tree attaining a height of from 40 to 50 feet, and is now being cultivated very generally and plentifully in southern Europe both for shade and for the edible pods. The yield of these pods per tree is often great Some trees frequently produce as much as 800 or 900 pounds

The carob tree does not stand frost but it grows well in dry rock soil and should prove a valuable acquisition for planting in parts of the southern States. The United States Department of Agriculture, has, from time to time, propagated and distributed many hundreds of young carob trees, chiefly in Texas, Florida and in other southern States. In order to encourage its cultivation in Florida, the department propagated it in the experiment garden at Miami, Florida In response to numerous requests received from farmers and others, the station distributed seeds and cuttings, and a number of healthy young plants are now growing in the southern part of the State. This valuable tree has been tested also in southern California, and its culture doubtless, will become quite general, because there is no other tree that is likely to become more popular for shade and ornament in dry, rocky situations than the carob tree It can not only be trained into a very ornamental shade tree, but may be planted as a wind break to more tender vegetation. Its introduction into southern New Mexico and Arizona has been recommended as an important addition to the food supply for stock in those States. Occasional trees are now growing around San Antonio, Texas.

The carob trees is at present cultivated in all warm countries which suffer from periodical droughts, its long roots penetrating to a great depth in search for water It will grow in almost any kind of soil, provided it is thoroughly drained. In southern Florida it grows very rapidly on the dry shallow soil underlaid with the porous oolitic limestone. It is said to prefer limestone soil, but it will flourish on almost pure sand or on rich alluvial soil The carob tree is very common in some parts of the Canary Islands, and in 1888 was introduced to Jamaica Its introduction into the semi arid parts of Chile and Argentina has been attended with considerable success. It is grown also very extensively in South Africa, Australia, and Sandwich Islands. In all these countries the carob tree can be grown in places where no other trees will grow, notably on the dry arid regions, and it seems certain that in the endless varieties of soil and climate found in southern New Mexico and Arizona there must be many districts where it would prove very successful. The introduction of this tree would be simply invaluable to the people along the Rio Grande, especially at times when forage for their stock is scarce. Not only does the carob tree furnish food for horses, but also shade for cattle and sheep.

In practically all tropical and subtropical countries the tree is cultivated extensively for the pods which form an important article of trade. The fruit is a dark brown leathery pod of from 4 to 10 inches long and often an inch or more wide, but not over a quarter of an inch in thickness. It contains a gummy, pulpy substance of an agreeable sweet taste, which renders the pods an important article of food for the poorer classes wherever the tree grows. Although the edible portion of these pods contains about 60 per cent of sugar, it possesses very little real nutritive value, the saccharine matter belonging to the class of foods called carbonaceous, the seeds alone possess nitrogenous matter, and these are flat, hard, shining-brown, about the size of a lentil and cannot always be readily masticated. In recent years these pods have been imported into England and the United States, and have become a common article of sale in the small shops of the poorer neighborhoods of London and New York, where the children purchase them for the sake of the sweet pulp which surrounds the seeds. Large quantities of these pods have been imported into England as food for horses, and it forms one of the chief ingredients in the patent cattle foods. The value of the carob beans exported from Cyprus, an island in the Mediterranean Sea, has in some years reached over $390,000. Not only are the pods valuable, but every part of the tree is useful. The wood is hard, heavy and is very durable in contact with earth and water

The carob tree is propagated usually by seed, which is the most natural and also the easiest method. Propagation by layers, cuttings or grafting may be advisable if one wishes to be sure to grow a special variety, of which there are a number, but to make a start in carob culture it will be best to plant the seed, and other methods can be attempted later The best time to plant the seed is in August. The covering of the seed is very hard, and in order to hasten germination it is recommended to place them in hot water (not boiling) until they are softened, which may take from 2 to 10 days. When this is done the seeds should be planted at once in their permanent places. In this event, the young plants must be watered regularly and kept free from weeds until they are old enough to take care of themselves. When cuttings are used these should be prepared about 6 inches long from matured one-year-old wood in March or April. The advantage of propagating the carob tree by cuttings is that fruit bearing trees can be selected and in this way regulate the number of male and female trees. To insure the fertilization of the female flowers there should be from one to two males to every 50 female trees. Those who cultivate the carob trees in the Orient usually keep bees, because it is by means of these insects that a great many flowers are fertilized.

The distance the trees should be planted apart depends upon the local conditions, and the object of the plantation. If it is planted for a wind break, 8 feet apart will probably not be too close. In cases where it is desired to grow large trees for the fruit they produce, 30 feet each way is recommended.

Motor Trucks Articles in Next Week's Scientific American

THE subject of the automobile is now so big that it is impossible even in an enlarged issue of the Scientific American to discuss all its phases. In this number we have confined ourselves entirely to pleasure cars. Since the motor truck cannot be ignored, we will devote to it considerable space in next week's Scientific American In that issue the reader will find a general article in which the capabilities of motor trucks are graphically compared with the capabilities of horse-drawn vehicles in one of those comparative drawings which were invented by the Scientific American many years ago, and which tell their story more tellingly than words. There will also be a table of motor trucks similar to that of gasoline and electric pleasure cars to be found this issue on pages 44 and 46, but in that table motor trucks will be classified, not according to price, but according to their capacity

Preventing Oil Cloth from Cracking

A GOOD way to prevent oil cloth from cracking when used as covers for tables is as follows. A few thicknesses of paper are placed on the table and moistened thoroughly with machine oil. This will cause the oil cloth to last much longer, [illegible], and prevent cracking of the glazed surface. It should be stretched tightly over the [illegible].

No-Rim-Cut Tires
10% Oversize
By Far Outsell All Others

This Winter Tread
Will Indicate Why the Goodyear Won

Last year we sold 918,687 automobile tires.

Yet we failed to keep up with the flood-like demand by some 400,000 tires.

Seven years ago only one tire in ninety was a Goodyear tire.

Three years ago the demand was still one-twelfth as large as now.

Last year's sales by far exceeded our previous 12 years put together.

What has awakened men to Goodyear tires in this overwhelming way?

This winter tread will tell you. It shows how far we go, in every way, to multiply efficiency. To cut down tire expense.

This is only one item, but it reveals the entire Goodyear code.

Compare this tread with others, and you'll see why Goodyears won.

Note the Double Thickness

In this Non-Skid tire we add an extra tread almost as thick as the regular Thus we give you a double-thick tread

This extra tread is of very tough rubber, immensely enduring, almost impervious to wear

Because of its thickness, the blocks are deep cut. Their non-skid efficiency lasts for thousands of miles

A Bulldog Grip

These sharp-cut blocks present to the road surface countless edges and angles.

They grasp the road in every direction with a fairly irresistible grip

But the greatest advantage lies in the fact that these blocks widen out, so they meet at the base

They are not separate projections, which center the strain on a small part of the fabric They distribute the strain exactly the same as with smooth-tread tires That's the main reason why the Goodyear Non-Skid gives such exceptional mileage

Compare this tread with others.

Compare its thickness, the depth of its projections. Compare the apparent efficiency, due to these sharp-cut blocks.

Compare the way in which strains are distributed so the fabric can't be broken One glance will show you that this Non-Skid surpasses anything else of its kind About 250,000 of these treads have already been tested out.

Other Troubles Ended

Thus we have ended skidding troubles in the most effective way

Years ago we ended rim-cutting, just as completely, just as efficiently

Our patent tire—the No-Rim-Cut tire—has made rim cutting simply impossible

And that alone cut tire expense 25 per cent

Our 10 per cent oversize, under average conditions, adds 25 per cent to the tire mileage

Our fourteen years of ceaseless tests and comparisons have brought our tire quality up to the maximum

These things together, in the test of time, have placed the Goodyears on at least a quarter million cars.

One Must Respect This Verdict

Remember, please, that tire expense forms your major cost of upkeep

A tire which cuts that cost in two is something quite important

Men know when they get it in these days of odometers They know which tire serves best And the final verdict of these men who know favors Goodyear tires.

Men have tried and compared now pretty close to 2,000,000 Goodyear tires As a result the sale of these tires has doubled every year And last year's increase was 125 per cent

Now these tires by far outsell all others. And this year's output, if this increase continues, will completely equip 500,000 cars

One may easily question any maker's claims. But when hundreds of thousands of users unite, one must respect their verdict.

The verdict of experience favors Goodyear tires in an overwhelming way And every month makes the verdict more convincing

Is it not fair to suppose that your experience will bring a like result?

If you think so, get that experience Make some comparisons Settle this question by next time insisting on Goodyear No-Rim-Cut tires.

Write for the Goodyear Tire Book—14th-year edition. It tells all that we know, after fourteen years, about cutting down tire expense.

What Gasoline Pleasure Car Can I Buy?

A Composite Price List of American Pleasure Cars

Compiled by Theodore M R von Keler

AS long as the motor car remained a luxury for the few the question of price was a secondary consideration. Quality speed and power were the chief points which the intending purchaser considered. A few hundred dollars more or less both in first cost and in upkeep expenses, made little difference to the man desirous of possessing an automobile. Conditions have changed. It is the man of moderate means—the professional man, small merchant and fairly well to do farmer—who is the best customer of the automobile dealer. To him the question of price is usually a very essential one. With a view to assist him in a choice of cars suited to his pocketbook, the price list below has been compiled.

Because of the complexity of the undertaking the list is not complete. It does not include the manufacturer whose whole output during the past year did not reach 100 cars. It does not include every model turned out by the manufacturers listed, it does not include new models announced after January 1st, 1913. It does, however, include the leading types of cars turned out by 131 manufacturers, with prices revised up to and including January 1st, 1913. Wherever further information as to other types is desired, a request to the manufacturers will bring complete details, catalogues and specifications.

Name of Car	Name and Address of Manufacturer	Under $600	$600 to $1 000	$1 001 to $1,500	$1,501 to $2 000	$2 001 to $2 500	$2 501 to $3 000	$3 001 to $4,000	$4,001 to $5 000	Over $5,000

The Trend in Automobile Construction

The Views of Automobile Engineers and Designers

Some weeks ago the Editor of the SCIENTIFIC AMERICAN *sent out a letter to the members of the Society of Automobile Engineers in which they were asked to give their views on present tendencies in automobile design. Through lack of space it is impossible to publish all the replies received. Moreover, automobile engineers are fairly well agreed on the present tendencies, so that there would be considerable repetition were all the replies printed. It has been deemed advisable to select from the many letters received those which seem to express the views of most designers. In this selection subject matter has been considered rather than the personality of the writer. More replies appear in the current issue of the* SCIENTIFIC AMERICAN SUPPLEMENT.—EDITOR.

We believe present tendencies in design and construction are for smaller motors, higher speed and more efficiency than found in the present type of motor motors that would compare with the better design of motors on the other side, small high speed, highly efficient motors are used. This seems to be a vital subject, as the price of gasoline is steadily going up and therefore the economy must be closely watched. Also there is a very strong demand for automobiles using a high grade of kerosene or a low grade of gasoline and this is something that must be met and handled by the engine builders as well as the carburetor manufacturers.

GEORGE T BRIGGS
Indianapolis Wheeler & Schebler.

The electric starter is giving the engineer considerable concern. The electric starter must be reliable, self controlled and above all fool proof. It must be large enough to crank the motor rapidly and yet as small as possible in order to keep down weight. The charging and lighting dynamo, whether it be one unit with the starting motor or a separate machine must have sufficient capacity to keep the battery fully charged at all times, and must of course be small enough to keep down weight. It becomes evident then that the ideal electric equipment is the combination of the charging dynamo with the starting motor in one unit, thus giving one half the added weight.

CHARLES BRYDEN *Chief Engineer*,
Indianapolis, Ind American Motors Company

The automobile manufacturer is giving his careful attention to the public demands for a comfortable noiseless car, particular attention being given to self starter, the tendency being in favor of the electric self starter.

The manufacturer to-day is giving greater attention to the analysis of metal used and in most instances specifies his own analysis as he has learned by practical experience that certain analyses give better results for his particular kind of work.

P J IMOATE,
Detroit Mich Heinze Electric Company

First of all the present tendencies in the design of engines is in the application of the long stroke and some type of piston or sleeve valve to replace the poppet types. In regard to the design of carburetors, which is, of course an other important problem that confronts automobile engineers most strongly is the adaptation of present successful types to operation with kerosene or at least liquid fuels heavier than gasoline. Variations in the design of the valves are however very insignificant in comparison with remodeling of the carburetors for automobile engines. This tendency is observed on every hand by the widespread interest in all sorts of devices being proposed for using heavier liquid fuels and by the improvements made in most of the 1913 models of carburetors for heating the mixing chamber either with the hot water from the jackets or with the exhaust gases.

J A MOYER,
Professor of Mechanical Engineering,
State College Pa Pennsylvania State College.

The most vital problem to-day in the gasoline automobile is the necessity of being able to burn the poor grades of fuel. The greatest want to-day is the ability to burn kerosene successfully in the present automobile engine. The most serious problem to-day is the lack of gasoline. 1913 and 1914 will be more serious in this respect than at present.

H S HOMMY
Waukesha Wis. Waukesha Motor Company

One of the problems that seems of great and almost imperative importance and in which the requirements for a solution are continually becoming more pressing is, of course, the carburetor and fuel supply.

The difficulties are known but the incentive to remedy them does not seem to be sufficient. Many data are required before the engineer may command this subject. The data are wanting. The defects are known but the remedies not. The law of diffusion of vapors is but little understood, and if it were understood, the engineer does not know what sort of vapors he is dealing with. The relations between the carburetor and the motor and different speeds of the motor length of the intake pipe and such matters have not been thoroughly investigated.

Detroit, Mich E. J STODDARD

The present day demands of the owner driver in the order of their importance are as follows: Electric lighting self starting motor magneto ignition extreme quietness at all speeds, flexibility of control maximum ease alighting from driver's seat, convenience of minor controls, ability to completely lock up car, liberal oil storage for hundreds of miles of running.

Accessories.—Top capable of raising and lowering without help and curtains lowered from within. Glass front adjustable from completely lowered to rain vision. Demountable rims with extra rims, casings and tubes.

Chicago, Ill. R. M NEWBOLD.

From the manufacturers standpoint, the present tendencies in design and construction may best be summed up as developing along two lines (*a*) the more economical use of material (*b*) the more economical distribution of material.

By the more economical use of material we mean the use of such special alloys or specially treated materials as shall produce a car which is more durable, requires less attention and weighs less for a given carrying capacity. By the more economical distribution of material, we mean the careful study of design in every part of the car in order that the best material for any particular part shall be used in that part, that no more shall be used than is requisite to have it perform its due and proper functions.

A P BRUSH, *Consulting Engineer*,
Flint, Mich. General Motors Company

As to present tendencies in carburetor design, in Europe they have done away with the spring air valve and alt have all the air entering past the point of fuel flow. This tendency is being widely felt in this country and the makers are gradually coming to this type.

The public are demanding carburetors which start easier and keep on running even after motor and carburetor are very cold.

GEORGE M HOLLEY *President*,
Detroit, Mich. Holley Brothers Company

The latest field for experiment on the part of the engineering department is demountable wire wheels. It is the writer's opinion, however, that this foreign feature will eventually consist of non-demountable wire wheels, fitted with demountable rims for quick detachable tires, because the expense of additional spare wheels, as well as the weight, more than compensates for the advantages resulting from the use of wire wheels.

Among the advantages of wire wheels compared with wood or pressed steel wheels, are increased tire wear, due to the resiliency of wire wheels, and improved appearance of the car. The subject of braking all four wheels has been discussed a number of times by American engineers, but has not found favor in this country and is losing favor abroad.

Relative to bodies, the growing tendency is for straight line flush side construction with a stream line effect in order to reduce wind resistance to a minimum.

New York, N Y JOSEPH A ANGLADA.

I feel that the present tendencies in design and construction, if left to the manufacturer would be simplification of parts and ease of assembly. The demands of the public, however preclude the possibility of working very far in this direction.

There seems to be a tendency to use wire wheels. I hardly think that the demand for this, however is caused by any trouble that the wood wheel has given but it is due more to a desire for something newer. It is a fact however, that some of the larger concerns in England are putting more than half of their product on wire wheels.

C A TRASK (Per R. P), *Assistant General Manager*,
Indianapolis. Henderson Motor Car Company

It seems to me that the most vital problems are the development of engines and carburetors to use kerosene and alcohol successfully, a simple and successful substitute for the poppet valve, the proper design and lubrication of small bearings and linkage joints.

It seems to me that with the substitution of a simple and successful sleeve or rotary valve, the addition of means for using a heavy fuel, and adequate protection and lubrication for small wearing parts, the present moderate-priced machines would be all that could be desired.

D W SMITH, *Member S A E*,
Washington D C Brock, Recken & Smith.

The present tendencies in design and construction are toward quietness, simplicity of arrangement of parts, luxuriousness and electrical improvements.

The public demand is for higher powered cars, 6 cylinders, electric lighting, easy riding, full equipment and accessibility.

The demands of the public must be met by decrease in the cost of production without sacrificing the quality of the cars produced, better design from the standpoint of the engineer, reduction of selling costs and standardization of certain parts.

The vital problems in automobile construction are those affecting the maintenance of the car such as carburetors, transmission gearing, lubrication and tires.

Every concern should pay special attention to the establishment and maintaining of a properly equipped laboratory under the supervision of an engineer who has been thoroughly trained in the theory and practice of motor car construction, both at home and abroad.

W C MARSHALL,
Assistant Professor of Machine Design,
Sheffield Scientific School of Yale University
New Haven, Conn.

The tendency of the automobile construction at the present time, appears to be the substitution of spline shafts for square shafts in transmission boxes. This is desirable, in a general way provided the making of the shaft and the gear is carried out on correct lines, that is, the spline shaft should be made so that the surfaces between the splines run true with the bearings, and then the hole in the gear could be ground to proper diameter to fit this shaft at its smallest diameter and accurate results can be obtained.

There is a tendency among some of the manufacturers to have the gear make contact on the tops of the splines, because this surface can be easily machined by putting the shaft in a plain grinder and grinding the tops of the splines after the shaft has been hardened or heat-treated.

The ideal way, we believe, is to finish the spline shafts accurately between the splines either by a second milling operation or by a grinding operation, and then design the gear to fit on this surface and not fit on the tops of the splines. By so doing, the gear can be ground to accurate diameter on an internal grinding machine and perfect fits are sure, together with accurate workmanship and quiet running operation.

JAMES N. HEALD,
Worcester, Mass. The Heald Machine Company.

An Ingenious Overheating Tell-tale

ALTHOUGH the automobile motor admittedly is a heat engine, and as such requires to operate at temperatures which under ordinary conditions would be considered comparatively high, it still is essential that this temperature be controlled within well-defined limits if the motor is to operate at its maximum efficiency

In other words, the amount of heat that is dissipated, or, figuratively speaking, lost, determines the thermal efficiency of the motor If the motor runs too cool, its efficiency will be low, as will be directly visible in the increased amount of fuel required to generate a given amount of power Theoretically, its thermal efficiency will increase in proportion to the temperature rise up to a certain limit when the permissible co-efficient of expansion of the metal parts is reached when there is danger that the pistons will 'freeze" in the cylinders and cause damage that is costly if not irreparable. Needless to add, motors are particularly susceptible to danger of the kind during the summer season

As a rule, the water cooling system can be relied upon absolutely to maintain a motor at the proper temperature for the best all around results. There are conditions, however, as when making long climbs on low gear, for instance, when the temperature rise may be abnormal Also, a broken fan belt, of which the driver may have no knowledge, or a short age of water in the radiator, may cause excessive heat

To give the driver instant and visible evidence of such conditions, an ingenious radiator thermometer has been developed and recently placed on the market. In its simplest aspect, it consists of a short thermometer tube containing bright red liquid mounted on a short scale with wide plainly marked divisions. At the upper end of the scale, between the divisions 130 and 212 deg Fahr., there is a round aperture the purpose of which is to permit the driver to see the red fluid instantly it mounts higher than the division corresponding to a temperature of 130 degrees. At approximately 180 degrees, which is the normal operating temperature of the average motor, there are two arrows, one on either side of the scale, so arranged that the driver is made instantly acquainted with further temperature rises, which may be taken as an indication of improper driving or derangement in the cooling system.

The device is calculated to detect leaky radiators, water shortage loose or broken fan belts, faulty lubrication, etc., all of which are conducive to over heating In cidentally, it should prove valuable in increasing fuel economy, for it is comparatively well known that very few motors are operated on the minimum amount of fuel, rich mixtures are one of the most prolific causes of excessive temperature rises.

The thermometer scale registers, also, down to the freezing point of water, and the instrument, therefore, should be useful in obviating the conditions which otherwise would result in the cooling system freezing up in cold weather With its aid, the driver is enabled to tell at a glance just when to throw his robe over the radiator while waiting for passengers, or, instead of permitting his motor to run idly for long periods, thus reducing fuel economy, he can stop it until the temperature of the water as indicated by the instrument, becomes low enough for the motor to be started and run for a short time to heat the water above the danger point again.

The device can be attached to any motor merely by drilling a three eighths inch hole in the radiator cap and inserting the stem of the device through it.

The Automobile Bus in Europe

IN various parts of Europe the use of the autobus for passenger service is on the increase. We note that in Greece the government wishes to have the public service running as soon as possible between Tripolitza and Sparta and between Lamia and Karpenissos. In Paris the

INQUIRY COLUMN

Inquiry No 9291 Want to buy machinery for manufacturing wooden tooth picks.

Inquiry No. 9292 Wanted a gum that will stick labels to grape-fruit

Inquiry No. 9293 Wanted the names and addresses of manufacturers of waterproof cloth, also samples of such cloth

Inquiry No. 9294 Wanted to buy glass balls 1¼ x 1¼" in diameter

General Omnibus Company is now finishing the entire change-over, and the last of the double-deck horse vehicles are now disappearing. The figures for the last week of July showed 2,155 autobus running regularly in London, and 800 of these were put in use since the first of the year. The company is beginning to use several autobus of a new type for special service on renting by private parties, containing 27 or 34 places, and they are now running a new line which ends at Windsor, covering 12 miles in 1 hour and 18 minutes.

The New Vienna Museum of Technology and the Industrial Arts

THE first general assembly of the "Technisches Museum fuer Industrie und Gewerbe in Wien" met in the municipal council chamber of Vienna on December 1st. The meeting was attended by many manufacturers, scientists, technicians, financiers and public officials, whose interest in the new foundation had drawn them to the capital from all parts of the Austro-Hungarian empire.

The nature, purpose, preliminary history and present condition of the museum may be gathered from the addresses made by various speakers, including Arthur Krupp, chairman of the working committee which has had the affairs of the museum in its charge.

Herr Krupp, in his opening address, reminded his hearers that the Museum had been planned as a permanent memorial of the Jubilee Exposition held in Vienna in 1908, and that the establishment of such a museum had been suggested in 1907 by Dr. Brosche then attached to the ministry of commerce, for the purpose of stimulating interest in the projected exposition, which appeared to be in danger of failure. The great industrial companies and firms adopted the suggestion with enthusiasm, and a working committee was formed to take charge of the preliminary work. The Imperial government granted the museum a subvention of 1 500 000 kronen ($305,000) and agreed to incorporate with it a number of important government collections. The city of Vienna contributed a suitable building site and a large sum of money.

The Imperial minister of commerce, after referring to the importance of technical progress for natural prosperity and the rapid and continuous transformation of industrial methods by the application of new advances in science and technology welcomed the museum especially as an evidence of the part pledged in these advances by Austrian investigators—a part often underestimated even in their own country. The speaker claimed the invention of the screw propeller for the Austrian inventor, Ressel. He then spoke of the educational value of the museum, in which the progress of an invention can be followed from its crude beginning to its finished and practical form. Here the curious visitor and the embryo inventor will see the original Bell telephone beside the newest and most convenient desk instrument, the feeble little locomotive of old beside the latest, swiftest and most powerful giant of the rail, etc. The minister of commerce praised the generosity of the city of Vienna which had given a million kronen and land worth another million, and the 800 firms and individuals who had contributed more than two million kronen, this increasing the total endowment to 4.6 million kronen ($934,000). The government had chosen eminent men as its representatives in the boards of directors and curators, and had appointed Herr Arthur Krupp president of the board of curators.

President Krupp, before moving to proceed to the election of curators, stated that the universities, technical schools and scientific societies would have special representatives on the board, and that the general association of the museum already numbered 1,050 members.

The museum building is nearly completed, and the work of interior arrangement, equipment and installation of collections will probably be completed within a few months.

Will the Automobile be Driven by Kerosene?

(Concluded from page 51)

The test showed the following figures

	Consumption in pints	Cost cents a pint	Horse-power cost, cents
Gasoline engine			
Fuel	0 70	1 372	1 067
Oil	0 09	8 375	0 203
			1 260
Diesel engine			
Fuel	0 80	0 508	0 366
Oil	0 08	8 375	0 305
			0 671
Automobile engine Kerosene (G C device)			
Fuel	0 65	0 627	0 488
Oil	0 018	8 375	0 183
			0 671

Among the devices made in America which have proven successful, mention must be made of the Universal, Holley, Hart-Parr (tractor), Twombly, International Harvester (tractor) Rumely (tractor), Gas Traction (tractor) Mietz & Weiss (stationary), Hornby Ackroyd Dehi Vergne (stationary) A number are still in the experimental state

In his experiments, Mr Holley has found that a Ford car fitted with his device will give 28 miles a gallon on kerosene and 32 on gasoline as bought at random in Detroit. This is a per mile cost of 0.35 cent for kerosene and 0.6 cent for gasoline (based on 10 and 20 cents) Mr Holley states as a result of several years experimentation in this line that he believes "the kerosene carburetor will be used largely in the commercial line, such as delivery wagons, motor trucks and commercial boats at an early date. As to motorcycles and pleasure vehicles, it has a future but gasoline will be used for a considerable period"

The makers of the Universal state in their guarantee that "The device will give a greater range of speed control than cold gasoline and a range equal to heated gasoline, that it will give from 10 to 15 per cent more power a pound of fuel on kerosene than on gasoline, and back up both claims

These instructions and the foregoing seem to show that there is a big future in kerosene as an automobile or internal combustion engine fuel, and that its use is not far away, nor will it entail any great amount of change in existing motors, other than the substitution of a suitable vaporizer

TABLE OF COMPARATIVE KEROSENE AND GASOLINE RESULTS TAKEN FROM WINNIPEG AGRICULTURAL TRIALS 1912

Fuel Make, Entry Number Class, Type and Size Engine Plows, Mileage Traveled	Fuel in Pounds	Cost of Fuel an Acre Plowed	2-Hour Brake Test: Average BHP	Fuel in Pounds	Cost in Cents—Fuel—BHP. Hour	HP-Hours of a Gallon of Fuel	HP-Hours of $1 00 Worth of Fuel

Decrease in price of Gasoline, which is unfavorable to Kerosene 2 5 per cent.

The Making of a Pneumatic Automobile Tire

(Concluded from page 2.)

Spreading and Calendering.

Rubber which is used for the general line of molded goods, solid tires, some kinds of tubing, etc., goes directly to the various departments from the green-stock storeroom, while rubber used for boots and shoes, waterproof fabrics, many of the druggists' sundries, belting, pneumatic tires, inner tubes, etc., has to be sheeted out, and some of it forced into fabric before it goes to the various departments. This sheeting-out of the gum, as well as applying the rubber to fabrics, is done generally by two methods; either by spreading a solution of the rubber and spreading onto the fabric, or by calendering the rubber between heavy rolls in a rubber calender

In the spreading process, a machine called a spreader is used The fabric to which the rubber is to be applied is mounted in a roll at one end of the spreader and from the roll passes through a trough of rubber cement, and then up over a so-called doctor roll, and under a knife edge, which allows only enough cement to pass through to fill the pores of the fabric From this knife the cemented fabric passes over a steam drying chest and is then rolled up with a roll of liner cloth to prevent its sticking together Fabric thus treated must be put through the spreader a number of times before it

has accumulated rubber to be used in the products for which it is intended.

For calendering rubber, a machine called a rubber calender is used. This machine is made with three and sometimes four heavy rolls, capable of very fine adjustment. The rubber from the green-stock storeroom is first warmed up on a small mixing mill and is then fed between the rolls of the calender, coming through in a thin sheet of required thickness, and is wound up in a liner cloth and sent directly to the departments, where it is used for inner tubes, druggists' sundries, etc., where only rubber and no fabric is used. Where the rubber is to be applied to fabric, the fabric is put through the calender rolls with the rubber, and the rubber is literally ground into the fabric. Fabric thus treated is known to the trade as friction, and is generally used in the manufacture of pneumatic tires, belting, hose, etc. For boots, shoes, and other special work, calenders are used which are equipped with rolls engraved with the shapes of the soles and other parts of the articles in question, so that the sheet of rubber coming from the machine has imprinted on it the shapes and thickness of the articles for which it is intended.

After passing through such of the processes described as are required the rubber is ready to be made up into the various articles known to the rubber trade, such as boots and shoes, mackintoshes, waterproof fabrics for balloons, aeroplanes, tentings, etc., mechanical goods such as rubber heels, horseshoe pads, packing, tiling automobile and other bumpers, artificial fish bait, etc., druggists' sundries, such as nursing bottles, nipples, syringes, bulbs, hot water bottles, tubing, etc., tobacco pouches, rubber belting, golf and other balls, insulated wire, fire and garden hose, inner tubes tires and the many other commodities into the manufacture of which rubber enters. As this article has to do more especially with the manufacture of automobile pneumatic tires, we will omit the various methods used in the manufacture of the numerous articles mentioned above and pass directly to the manufacture of pneumatic motor car tires and inner tubes.

When the first pleasure automobiles were made in any quantities the tire used was of the single tube type and fastened to a crescent shaped rim by means of lugs or bolts, and cement This proved very unsatisfactory, and the clincher type tire, using an inner tube then came into prominence as an automobile tire With some variations in design, this type of tire still continues to be vary popular, but during the growth of the automobile industry, the so-called straight-sided or detachable automobile tires have been developed, and have come into favor Some of the latter type of tire are of the regulation Dunlop type, others being somewhat different Most all of these so-called straight sided tires have wires in the beads to keep them from flying off the rim. With the development of the motor truck industry, solid tires have come to be used where heavy loads have to be carried. This type of tire has been developed from the original wagon tire to the present various types of improved motor truck tires, and so-called high efficiency solid tires, of peculiar design, to give the desired resiliency and wearing qualities.

The Birth of an Automobile Tire.

From the calender room of the rubber factory, the stock is received in the automobile tire department, in the form of large rolls of rubber coated fabric, and in rolls of sheeted rubber of various thicknesses and widths. The rubber coated fabric is first cut into strips of proper widths so that the edges will extend from bead to bead over the crown of the tire. These strips are always cut on the bias, generally at a 45-degree angle, with the edge of the roll, and were formerly all cut on a cutting table, a table about 50 feet long and 6 feet wide covered with sheet metal. The cutting was done by two men, each having a knife and each cutting half way across the cloth along

the edge of a straight-edge so arranged as to be always set at 45 degrees with the edge of the table. Gradually this method of cutting is being put aside by the use of the bias cutter, an extremely up-to-date machine having jaws which ride up to the end of the fabric and pull it for a certain distance under a knife set at a 45-degree angle, the knife being set to cut just when the jaws have arrived at the limit of their motion. The action is repeated so that the machine cuts about eighty strips a minute. These strips are fed onto a series of belts which carry them to where they are placed, by boys, into a book having a leaf of cotton cloth between each strip of gum fabric, to prevent the strips from sticking together.

The majority of automobile tires to-day are built by the hand method, and in this process the books of fabric are laid up and spliced into proper lengths to go around the tire and allow a proper lapping for the splices. The proper number of these laid up pieces, or plies, as they are called, are placed together with cotton cloth between and taken to the tire builder. The tire builder mounts the core, upon which the tire is to be built, on the building stand, generally cementing it so that the first ply of fabric will stick in place. The first ply is then stretched onto the core and spliced, rolled down with a hand roller onto the sides of the core, and trimmed with a knife at the base. The following plies are put on and rolled down in the same manner, the beads being put in at the proper time, according to the size and the number of plies to be used. After all the plies have been put onto the core, the so-called cover rubber is put on. This cover rubber is generally a sheet of rubber about one sixteenth of an inch thick or more and of the same compound as the rubber on the fabric.

In the case of the machine built tire, the result is the same, but the stock is handled as follows. After the rubber coated fabric has been cut on the bias cutter, the strips are spliced and rolled up in rolls on a spindle which is placed in the so-called tire building machine. The tire core is mounted on a stand attached to the machine so that it can be revolved by power and the fabric is drawn onto the core from the spindle under a certain definite tension. The tire machines roll the fabric down by power, and the beads are put into place before the tire and core are removed from the machine. Thereafter the process is the same as in the case of the hand-built tires.

After the cover rubber is in place the tire is ready to have the tread applied. The tread is made up independently of the tire by laying up narrow strips of rubber, in different widths, in such a way that the center of the tread is thicker than the edges. In the case of the so-called single cure tires, which are wholly vulcanized at one time, this tread is applied to the tire directly after the cover, a strip of fabric called the breaker-strip, generally being placed underneath, and the building of the tire so completed.

How the Tire is Cured.

In the general method of curing, the tire is allowed to remain on the core, and is either bolted up in a mold and put into an ordinary heater or it is laid in a mold and put into a heater press where the hydraulic pressure keeps the two halves of the mold forced together during the vulcanizing process. After the vulcanizing is completed, the tire is removed from the mold, the inside is painted with a French talc mixture, the tire inspected and cleaned, and so made ready for the market. In some methods of curing, the tire is put into a so-called toe-mold, which is virtually a pair of side flanges, reaching up only as high as the edges of the tread on the sides of the tire. After the flanges are fastened into place, the whole is cross-wrapped, the cross-wrapping coming in direct contact with the tread. The tire in this condition is then put into the heater and vulcanized, giving the so-called wrapped tread tire. Still another form of curing is to inflate a kind of canvas inner tube inside the tire and place the whole in a mold. This is known as the air-bag mold process.

From the case of the single curved tire just described, we will take up the case of the so-called double cure tire, in which the tire receives two separate vulcanizations. In this system of tire manufacture, the tire carcass is semi vulcanized before the tread is applied. This first vulcanization is always done with the tire on the core, and either bolted up in a mold or cured in a mold in a heater press, the period of vulcanization being only long enough to partially cure the rubber. The tire carcass is then taken from the mold and mounted on a buffing machine, and that part of the cover which is to be covered by the tread is buffed to a rough surface, which is then given one or more coats of rubber cement, allowed to dry, and the tread, which is generally made of some quick curing compound, is then applied in the green state. The tire is cross-wrapped, either by hand or by a cross-wrapping machine, placed in a regular heater and given the second cure. This second cure is timed to complete the cure of the carcass and also to completely cure the tread. After removal from the heater, the cross wrapping is stripped from the tire, the tire inspected, the inside painted, and so made ready for the trade.

Authorities differ as to whether the integral construction or single cure method or the semi-cure method produce the better results. Advocates of both systems are able to advance strong arguments in support of their respective methods.

The Three Kinds of Inner Tubes.

Inner tubes for pneumatic tires may be classed under three headings, according to the method used in their manufacture, viz., seamed tubes, rolled tubes, and tube-machine tubes. By far the greater number of tubes come under the first two headings. For seamed tubes, the rubber is taken from the calender in the form of sheets from 1/16 to 3/16 of an inch in thickness. These sheets are cut into strips of proper length and just wide enough to make a tube of proper cross-section diameter when the two long edges are folded over and fastened together with rubber cement. These two long edges are cut on a bevel so that they make a good lap seam. The tube is then pulled over a mandrel of proper size and a thin piece of wet cloth rolled around it and then it is spirally cross-wrapped with a long narrow piece of wet duck, for its entire length. The whole is then put into a regular heater and the tube vulcanized. After vulcanizing the wrapping is removed and the tube stripped from the mandrel, turning the tube inside out, so that the smooth side which was vulcanized next to the mandrel appears outside and the rough side showing the marks of the cross-wrapping, is inside. The valve hole is then punched in the tube, the valve inserted and the open ends of the tube buffed down to a feather edge. The tube in this state passes to the splicers, who cement the buffed ends and splice them together, placing one open end within the other making a lapped seam around the tube about 2½ inches long. The cement used in splicing is generally cured by an acid which chemically vulcanizes the rubber without the application of heat. The tube is thus finished and ready for the market. Rolled tubes are made from very thin sheet rubber by rolling the same over a mandrel of proper size, until the required number of layers of thin rubber have been rolled on to give the tube the desired thickness. The tube is then wrapped, cured, and spliced, in exactly the same manner as a seamed tube. Tube-machine tubes are run from a tube machine exactly like wagon tires, except that a die is used which permits the rubber to flow out in tube form. This tube is then pulled onto a mandrel, wrapped, cured and spliced, the same as the seamed and rolled tubes.

Europe's Good Roads

(Concluded from page 51.)

international thoroughfares in that they take note of the incomings and outgoings of all wheeled traffic, including automo-

biles, and are charged with the responsibility of seeing that driving licenses and registration and tax dues have been paid in the country of origin. The International Driving License, which has been put into use during the past couple of years, in no way precludes the obligation to conform to the demands of the customs officials and, in short, in one way or another this service works in conjunction with the roads control branches of the respective governments. On certain of the Swiss passes, all of them in fact that are open to automobile traffic, notably the Simplon and the Saint Gothard, a running time card, as it might be called, is issued by these same authorities limiting the passage over the mountain road to a certain pre-arranged time schedule, this in an attempt to regulate the speed on these dangerous mountain roads and as such it certainly does work effectively, as one is not let out at the other end if he arrives before the hour indicated on the permit.

Taxation of rubber tired traffic abroad is generally far in excess of what it is in America, but in France it does not go specifically toward road building or even amelioration, but is paid into the general coffers of the national treasury Including bicycles (of which there are three million circulating in France) there is contributed a sum equal to nearly three million dollars per year When the day comes—and there are signs visible which point that way—that this sum entire, save the costs of collection, is devoted to the building of automobile boulevards, call them by what name you will, at any rate thoroughfares intended only for fast traffic, France may be expected to double her lead over all countries of Europe as the automobilist's paradise. In this connection it is worthy of regard that automobile registration in France is considerably less than a hundred thousand vehicles, the largest French manufacturer producing only something like seven thousand chassis in a twelvemonth The result is that there are six miles of the finest road way on earth for each automobile that rolls over them. Some American manufacturer with a desire to pose as the real populariser of the automobile, *à la portée de tout le monde*, as the French say, has only to follow in the footsteps of the exploiters of the kodak to find himself in touch with a world market which has as yet only been scraped over

Partnership Use of a Motor Car

By P. H McKilwin

SINCE there are a great many persons who have been deterred from buying and using automobiles by the cost of running and maintaining them, the suggestion that two or more men go into partnership in the ownership of a car and divide both the cost of the machine and the expense of using it offers a possible solution of the problem that confronts thousands who greatly desire to enjoy the pleasures of motoring but have not felt in position to do so

The idea is new but there are a number of cases of the kind, one on Long Island in which seven friendly neighbors in a suburban place bought a car which is kept in a public garage and used to take them from their homes to the railroad station in the mornings and to meet them at the station in the evening, in addition to this, each part owner is entitled to the use of the car one day each week

No doubt there are thousands of families that would gladly pay half or a third or quarter of the cost of buying and keeping an automobile, yet who would put off indefinitely the buying of a car for their own individual use

There are two fundamental plans on which copartnership ownership and use can be carried out The simplest is an even division of all expenses, irrespective of the personal equation, which has the advantage of rendering bookkeeping or account-keeping unnecessary and avoids disputes over liability for damage done by careless driving, inexperienced handling and various small abuses Under such an arrangement one owner may get more mileage out of the car and tires, carry more passengers and generally get a larger return for his money than his partner If the partners are particularly good friends or relatives and are indifferent to small differences of this kind, the matter of dual ownership is extremely simple But if, on the contrary, it is desired that neither shall pay less nor more than his use of the machine makes equitable, it becomes necessary to divide the expenses into fixed and variable charges The fixed charges include the cost of the car and of any equipment subsequently purchased, storage, insurance, and overhauling and repainting when these are agreed upon The variable charges are those due to actual use of the machine, such as gasoline, oil and other supplies, tire wear, cleaning and so forth

It is evident that the fixed charges should be divided equally, but the variable charges should be paid by the partners according to their actual use of the car and liability for them Thus, if the car is kept in a private garage, the bills for simple storage could be rendered monthly and paid equally by the owners or alternately as agreed upon, but the bills for washing, adjusting, polishing, gasoline, and oil should be rendered weekly so that each of the owners can pay the bill for the week during which he actually used the car This is on the assumption that the car is used alternate weeks by the copartners, which is likely to prove the most satisfactory arrangement.

In order to avoid misunderstanding, it is almost imperative that a carefully thought-out agreement be drawn up in duplicate and signed This would state definitely the weeks on which each owner would have the use of the car This gives each the advantage of an equal number of Saturdays and Sundays They can trade off their time when one or the other is to be away on business or vacation Should any differences arise over this or other matters, the obvious way out without causing ill feeling, is for one to offer to sell his interest or to buy his partner's.

A full line of insurance covering losses by fire, theft, accident or collision should be carried and the payment of the premium divided equally The policy should cover small losses as well as the major ones, which is possible under the "full coverage" clause provided by the insurance companies.

Tires, like gasoline, are consumed and the consumption bears a close relation to mileage and to the way in which the driver uses the car Therefore, it would probably be wise for each partner to keep a record of his mileage and pay his part of the tire bill on this basis. Repairs of punctures and blowouts would be chargeable to the one using the car at the time they occurred, except in cases where they resulted directly from cuts or other injuries known to have occurred while his partner was using the machine Damages impossible to trace clearly should be divided equally

Miscellaneous small repairs and replacements, which are not covered by the manufacturer's guarantee, would most equitably be charged against the one using the car at the time the fault developed Of course, a break might occur during B's use of the car as a result of some unusual strain occasioned while A had the machine out, but this is an eventuality as likely to occur one way as the other

A successful carrying out of the plan herein outlined is dependent upon the common sense and spirit of fairness that animate the parties to the arrangement. Each should constantly remember that he is entitled to only half the use of the machine and that his partner, by putting up with the same limited use and dual responsibility, is really making it possible for him to enjoy the use of a car at all

What the annual costs to each are likely to be may be estimated approximately from the following table of itemized cost of maintaining two different types of family touring car, one a four-passenger light car costing $1,150 and the other a five-passenger car of about double the weight and power costing $2,200

	$1180 Car Drives 8,806 Miles in Eleven Months.	$2200 Car Drives 9,400 Miles in Ten Months.
Gasoline	$87 68	$149 28
Oiling and greasing	26 49	48.87
Battery charging and lamp renewals	10 13	10.85
Storage	53.85	102.30
Washing and polishing	80.25	96.25
Tires, tire repair and depreciation	79.37	370 03
Miscellaneous repairs.	46.94	65 00
Sundries	26.85	55 71

	$499 01	$1 060.30
Interest at 6 per cent	69 00	132 00
Depreciation	550 00	800 00
	$1,118 01	$1 992 30

Special Resources of American Libraries

EVERY scholar will welcome with enthusiasm the latest publication of the United States Bureau of Education 'Special Collections in Libraries in the United States,' compiled by W Dawson Johnston, librarian of Columbia University and Isadore G Mudge reference librarian of the same institution

Inaccessible books are the bane of every seeker after knowledge The special bibliography only half solves the problem The time will come when no special bibliography will be considered wholly meritorious unless it contains in connection with the title of every rare book a list of the libraries in which the book is to be found, or if this imposes too much labor upon the bibliographer unless at least *one* copy of the book is thus located. With this improvement coupled with the modern system of interlibrary loans the bibliographic millenium will be pretty nearly attained

Pending such a consummation a hand book similar to that just published by the Bureau of Education is an admirable makeshift Here we find a list of libraries in which each department of knowledge is most fully represented, with sundry particulars as to the strength of each collection along a particular line

To illustrate with a few out of the-way topics If you are looking for the literature of philately, you find, by way of the index, that the Pittsburgh Carnegie Library has a philatelic collection of 342 books, pamphlets and periodicals donated in trust by the American Philatelic Society, while the Boston Public Library possesses 210 works on the same subject If you wish to investigate chess try the Library Company of Philadelphia This institution is the depository of Prof George Allen's chess library, containing 1 070 volumes, besides newspaper clippings, manuscripts, and pictures relating to the game. The literature of the whaling industry is represented by 750 volumes in the New Bedford, Mass., Free Public Library The Berkshire Athenæum, at Pittsfield, Mass., has a collection of addresses at agricultural fairs. Cornell University Library has a Petrarch collection of 3,700 volumes, and a Dante collection of 7,000 volumes (exceeded in importance, if at all, only by the collection in the Biblioteca Nazionale, in Florence) Williams College Library has 162 volumes relating to Phædrus. Harvard University has a collection of Yiddish literature numbering 4,800 volumes and 1,600 pamphlets. The Masonic Library of Cedar Rapids, Iowa, has the most important collection in the United States on freemasonry and related topics, which in 1898 numbered about 15,000 volumes, of which 5,000 were in foreign languages. The Library of the Supreme Council of the Ancient and Accepted Scottish Rite of Freemasonry, in Washington, has a collection of about 1,000 volumes on occult and allied subjects. And so on.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Of Interest to Farmers.

BEET TOPPER AND DIGGER.—J DEVEY, Lehi, Utah The object of the invention is to provide a simple and easily operated device for topping and digging, especially adapted for use in harvesting sugar beets, which will first top the beets while yet firmly held in the soil and will afterward dig them The present invention is an improvement over the prior patent, No 975,218, granted to Mr Devey

BEET DIGGER, CLEANER, AND ELEVATOR.—J DEVEY Lehi Utah The object here is to provide a device for use in connection with an improved topper and digger shown and described in a copending application Serial No 612,179 for lifting, cleaning and loading the beets topped and dug or loosened from the soil by the said improvement

KAFIR CORN HARVESTER.—S B PETER, 705 West 3rd St Pittsburg Kan In the present patent the invention is an improvement in Kafir corn harvesters, and has for its object the provision of a simple inexpensive device for use in attachment to an ordinary farm wagon for cutting the stalks of the corn to remove the valuable portion

FENDER ATTACHMENT FOR MOWING MACHINES.—S M MARTIN Heatherdale, Prince Edward Island Canada This attachment can be readily attached to a mowing machine An object of the inventor is the provision of a device which will be simple in construction, which can be swung out of the way when it is not desired to use the same and which is provided with an adjustable stop and shock absorbing mechanism

Of General Interest.

DISPLAY RACK.—CATHERINE HOLLAND, 88 Zeidler Ave Maspeth L I N Y This invention has particular reference to rack devices adapted especially for domestic use or in connection with private laundries, the primary object being to provide a rack embodying cheapness of construction, facility to knock down and set up, lightness for transportation purposes, and stability of position while being used.

PROCESS OF MANUFACTURING BEET SUGAR. V KOLARAK Owosso Mich An object of this invention is first to produce from decayed beets a juice with the highest purity possible when the purity of the beets is below 80 per cent A further object is to obtain a better lime cake than by the ordinary method

COMPOSITE BUILDING BEAM W P FRANCIS, 115 Marietta St Atlanta Ga The invention provides an economical and simplified construction provides anchoring devices for uniting the masonry and the metal structure the arrangement of which distributes uniformly the breaking of the strain over the entire structure

WINDOW.—R. B HARTSFIELD 210 W 114th St Manhattan New York N Y The invention relates to windows having stiles mounted to slide up and down, and sashes pivoted on the stiles to admit of turning the sashes on the stiles The aim of the invention is to provide a window arranged to permit of conveniently turning the sashes with a view to allow cleaning of the outer faces of the sashes from the inside of the room.

Hardware and Tools.

LATCH.—W LARSEN Westbrook Minn. The invention pertains to latches particularly adapted for use in connection with doors, gates and the like and the aim is to provide a device of this character which may be adapted with equal facility upon gates and doors which swing either toward the right or the left hand.

KEY LOCK.—L. B. HOWARD, P O Box 394, Los Angeles, Cal This device may be used to fasten door keys in place to absolutely prevent a burglar from removing or turning the key from the outside making it impossible to lock the door from the outside It will also prevent children from removing the key from the lock which is a source of great annoyance and causes the loss of many keys.

HOSE REEL.—C WAGNER, 587 Hudson St., New York, N Y This hose reel is more especially designed for use on stand pipes in buildings to permit of quickly unreeling the hose with the water turned on and allowing an almost instantaneous passage of the water through the hose as soon as a fire breaks out and water is turned on from the stand-pipe.

METAL WORKING SHEARS.—C. H. PRINCE, 123 East Ave., L. I City New York N Y The invention provides a pair of shears of compound leverage, the construction and arrangement being such that the handle levers of the shears are prevented from working loose, being pivotally mounted in housing carried by the blade ends.

Heating and Lighting.

BUILDING LIGHT.—J STANLEY, 446 Mott Ave Bronx, New York, N Y The intention here is to provide a building light for use on sidewalks, vault covers, area lights, sky lights and the like, and arranged to compensate for expansion and contraction, with a view to prevent breaking or cracking of the lenses.

IGNITER.—F THOMAS, 478 Pine St., San Francisco, Cal. This invention consists essentially of an igniting device and an actuating means for normally holding the device in a dormant position, the actuating means being sensitive to atmospheric conditions and being actuated on a fall in temperature of the surrounding atmosphere to ignite the device and to thus set an inflammable material on fire.

COOKING UTENSIL.—F D CALKINS, 89 Charlotte St., Detroit, Mich This utensil is in the nature of a foraminous vessel designed for use in steaming, boiling, etc, within an outer vessel The invention relates particularly to means for reinforcing the foraminated body by means which are extended at one end to serve as legs for supporting the vessel and at their other ends as fastening means for holding the lid in place

STOVE POLISHING MITTEN.—NELLIE M SPRINGHORN, Blue Point, L. I., N Y The object of the invention is to provide an improved stove polishing rubber mitten designed to enable the user to keep a blackened stove to fine polish without requiring re-blacking for a considerable time and to readily remove water grease spots, and other extraneous matter thus keeping the stove clean and nice for a very long time and without danger of rusting.

COMBINED KITCHEN CABINET AND CUPBOARD.—C F WELGE care of Welge Bros., Chester Ill. The permanent features of the cupboard are so arranged as to permit of the lower portion of the cupboard receiving and supporting a hinged lid provided on the cabinet. The lid forms the cover for a flour bin and for a kneading board which is solidly supported below the lid and conveniently located with respect to the bin

BED-FAN.—R. N CHRISTIAN 4457 Oakenwald Ave Chicago Ill This invention relates to improvements in automatic fans and air circulators, and has for its object to provide means whereby the air above a bed may be cooled and caused to circulate It consists principally of a series of flat horizontally disposed and spaced strips of flexible material arranged above a bed, said strips to have vertical movement at one end It can be used in offices, workshops, out door camps, and can be readily folded and packed away

Household Utilities.

SASH FASTENER.—O M FARNHAM Lincoln Maine The present invention has reference to sash fasteners, and is more particularly applicable to the character of sashes which are temporarily installed such as storm windows, or window screens for porches or structures of a similar character

Machines and Mechanical Devices.

MEANS FOR LAUNCHING TORPEDOES FROM THE SIDES OF SHIPS.—ALBERT E JONAS Fiume Austria Hungary This invention provides means for launching torpedoes from the sides of a submarine vessel a torpedo boat or other light vessel at any angle and by means of a torpedo launching frame jointed to the sides of the ship. The purpose is to insure that the torpedo shall exactly follow the direction imparted by the torpedo launching frame at the moment at which the latter is locked and to prevent any deviation due to the gyroscope becoming operative prematurely

PAPER POLISHING MACHINE.—H OSBORNE, 992 4th Ave., Brooklyn N Y This improvement relates generally to paper polishing machines and more particularly it is directed to a structure comprising coöperative parts whereby the pressure of the movable stone may be adjusted so that the operation of the parts may be rendered more efficient

AUTOMATIC FILTER PRESS.—R. LAMMON and R P HOLMES, Boulder City Western Australia Australia This machine is for use in separating the liquid from the solid portion of liquid pulp by means of pressure and compressed air and is particularly applicable to the treatment of ores in a fine state of division commonly known as slimes, in which the gold or silver is dissolved and taken into solution by means of chemical solvents

TUMBLER FINISHING MACHINE.—J J DENNING Gas City, Ind. This invention provides a structure whereby a tumbler or the like may be quickly polished or finished. Means provide for holding and rotating a tumbler associated with a universally pivoted buffing member designed to be braced against a tumbler while rotating for polishing the same

STARCHING MACHINE.—W B. BURT, care of Bloesser Heynemann Co., 77 Battery St., San Francisco, Cal The invention provides improvements in starching machines such as are used for starching collars, cuffs and other articles, and whereby a constant supply of starch is furnished to the working portion of the upper cylinder to allow starching at a single operation even if the article is of a length in excess of the circumference of the cylinder, thus greatly increasing the machine's output.

CAN HEAD LINING AND ROLLING MACHINE.—H L. GUENTHER, 273 N Ave. 22, Los Angeles, Cal. This machine is for use in placing liquid cement or other packing material onto the flanges of can heads, and to bend over the flange edges, to confine and hold

the packing material in place and to prevent the can heads from sticking one on the other when stacked for shipping or storage the said material after drying forming a lining or packing and when the can head is finally attached to the can body and the flange is crimped and compressed onto the can body then a can is produced having an air-tight double seam

Railways and Their Accessories.

BRAKE SHOE.—J M. WOODWICK 102 Church St Montgomery Ala. This improvement is in car wheel brake shoes and dressers, especially in that class of such devices wherein an insert of comparatively hard metal is combined with a body portion of softer metal and affords a wearing surface to operate upon the car wheel. The invention relates to certain improvements in the insert construction

Pertaining to Recreation

GAME APPARATUS—H G ROBINSON L. B. 1733 Salt Lake City Utah This game is similar to golf Marbles are used in place of golf balls, and a knocker instead of golf sticks is used this knocker of thin steel and having at one end a grip by which the said end of the knocker may be drawn back so that when it is freed it will hit the marble with sufficient force to propel it in the direction of the pocket which is pivoted so that it may be moved as desired

Pertaining to Vehicles.

SPRING WHEEL. E L. COLTRY R. F D Red Oak Iowa This improvement is in wheels which are provided with an elastic tire or tread formed of spring metal parts or members and intended as a substitute for the expensive pneumatic or solid rubber tires usually employed on the wheels of automobiles and other motor driven vehicles

SIGNALING DEVICE —CHARLES A SCHINDLER 287 Palisade Ave West Hoboken N J The invention relates to signaling devices such as shown and described in the Letters Patent of the U S. No 1,015,715 formerly granted to Mr Schindler The object of the present invention is to provide a device more especially designed for the use of chauffeurs and other drivers of vehicles and arranged to enable the user to readily give an audible signal during the day and a visible signal at night to a following vehicle whenever it is desired to turn out of the direction in which the vehicle is travelling or for other purposes. Use is made of a glove provided on one finger with spaced contacts either of which is adapted to be engaged by a circuit closing contact on an opposite finger the said contacts being in two electric circuits connected with a single source of electrical energy one circuit containing an electric lamp and the other an audible alarm

CART —F F WALTHER R F D Scribner Neb The object of the invention is to provide a simple cheaply constructed cart light in weight yet strong and nicely balanced and consequently of light draft With this improvement the horse can travel in a smooth path and the wheels will also travel in the beaten portion of the road By moving the seat to the proper position the body can be so balanced that the weight is taken off the horse's back

GEARING J F COLLINS 253 West 111st St Manhattan N Y., N Y This invention refers especially to gear casings adapted especially for automobile practice The casing secures greater facility in inspecting and making repairs in that type of automobile transmission mechanism in which are used both the slidable gear speed changing devices and the worm driven mechanism than has hitherto been possible

RESILIENT WHEEL T E VAN DER WERKEN care of C C Finch Surrogate's Office Green Island N Y The purpose here is to produce a vehicle wheel to resiliently support the load strains of a moving vehicle such as an automobile and to take up and cushion the shocks incident to the moving of the vehicle over uneven roads without the use of pneumatic tires.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each Please state the name of the patentee, title of the invention and date of this paper

WE wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade mark work Our staff is composed of mechanical electrical and chemical experts thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized technical, or scientific knowledge required therefor

We are prepared to render opinions as to validity or infringement of patents, or with regard to conflicts arising in trade mark and unfair competition matters

We also have associates throughout the world who assist in the prosecution of patent and trade mark applications filed in all countries foreign to the United States.

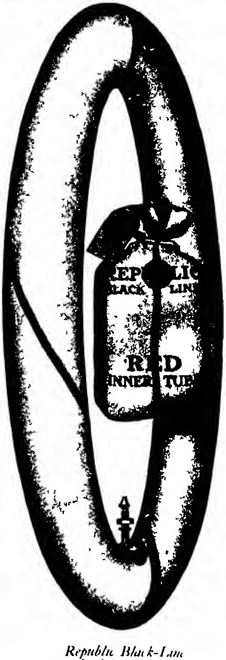
This is The Republic Rubber Company New Calender Room



Republic Black-Line Red Inner Tube

Where machines and brains make tire mileage for YOU

Republic Staggard Tread Tires give you the mileage you really ought to get because their foundation is *right*.

The foundation of a tire consists of alternate layers of fabric and rubber And the efficiency of any tire depends to a great extent upon the manner in which the fabric and rubber are treated and combined

The illustration above shows the Republic Calender Room—the new "rolling mill" of this rubber plant where foundations for Republic tires are made

In this great room man's skill and ingenuity and modern machinery combine to make the *right* foundation for Republic Tires Scientific, pains-taking care is exercised in every operation from testing and drying the fabric to calendering ("rolling") the rubber and combining the two under proper heat and pressure

And on this *right* foundation is put the Staggard Tread—the tread of extra thickness that leaves the full-thickness plain tread after the center studs eventually wear off

The Staggard Tread is protection against skidding, and really economical because of the extra mileage it gives you

Write today for beautiful folder on this wonderful new Calender Room

The Original Effective Non-Skid Tire

What Shows Don't Show

By R. E. Olds, Designer

You'll see the new model of Reo the Fifth at your local Automobile Show.

It will strike you as beautiful, luxurious, roomy—having every final touch.

But here are things you can't see. And they mean, in the end, more than all that shows.

Tire Mileage

Tires on a car form the chief item in upkeep. Tire-saving means more than all other savings together. Every old motorist knows this.

So this year I add 30 per cent to my tire cost, to add 65 per cent to the average tire mileage. I give you tires 34 x 4. Compare them with rival cars.

The usual tires on this type of car would more than double your tire cost, so tire makers say.

No Possible Flaws

The steel in this car is twice analyzed, to make sure it accords with my costly requirements.

The gears are tested in a crushing machine, to prove that each tooth will stand 75,000 pounds. This test is usually made with light hammers.

The springs are tested in another machine to stand 100,000 vibrations.

I use in this car 190 drop forgings. The average cost is twice that of steel castings.

But they give me lightness and strength. And hidden flaws can't occur in drop forgings.

The various parts of this car get a thousand inspections. Thus all the uncertainties are completely eradicated in building this Reo the Fifth.

No Broken Bearings

I use in this car 15 roller bearings. 11 of them Timken, 4 Hyatt High Duty.

They cost five times as much as the usual ball bearings. But good roller bearings don't break under strain.

No Overtax

It's the sudden shock which shows up a car's weakness, not the ordinary tests. And sudden shocks will come.

To withstand them I give to axles and driving parts 50 per cent over capacity. I have made them all ample for a 45 horsepower car.

To prove them out I run one of these cars for 10,000 miles, at top speed on rough roads. I met at its worst every possible road shock and not one important part gave out.

I use 14-inch brake drums. I use 2-inch, 7-leaf springs. I use costly steels—chrome nickel, vanadium, manganese—all to ward off an overtax. I place cost below safety in this Reo the Fifth.

No Troubles

That isn't quite true. All machines have their little troubles. But I've gone to the limit to save trouble with this car.

Each engine is tested 20 hours on the blocks, and 28 hours in the chassis. There are five long-continued tests.

My carburetor is doubly heated—with hot air and hot water—to save the troubles with low grade gasoline.

I use a $75 magneto to save ignition troubles. I use a centrifugal pump, instead of a syphon, to insure the water circulation. That costs about $10 extra.

Cars are built slowly and carefully, parts ground over and over. I limit my output to 50 cars daily, so nothing shall be slighted.

No Skimping

To make the car show my infinite pains, I give equal care to the finish.

The body has 17 coats. The luxurious upholstering is of genuine leather, filled with the best curled hair.

There are three electric lights, and the dashboard lights are flush. And the whole car, even under the hood, is fully nickel trimmed.

Center Control

Our center control is exclusive to this car. All the gear shifting is done by one small handle, completely out of the way. It is done by moving this handle only three inches in each of four directions.

Both brakes are operated by foot pedals. So no levers at all clog the way of the driver. And this permits of the left side drive.

No other center control will please a man who once discovers this.

Add $200 to My Cost

These extremes I figure add $200 to the necessary cost of this car.

They cut down our profits. They force us to factory efficiency. They compel us to build every part ourselves. And to minimize cost we build only one chassis.

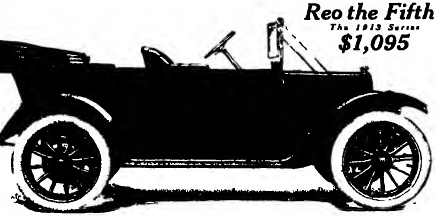
But these things save users from three to ten times what it costs me to give them to you.

They insure to you safety, economy, comfort. They insure to me that reputation I have spent 26 years in acquiring.

I find that car users, more and more, are coming to look for this class of car. Our output is always much oversold. And this year, with 60,000 excellent cars to my credit, the demand will be greater than ever.

A thousand dealers are now ready to show this new model of Reo the Fifth. Our 1913 catalog is also ready. Write us for it now.

Reo the Fifth
The 1913 Series
$1,095



30-35 Horsepower
Wheel Base—112 Inches
Tires 34 x 4 Inches
Center Control
Roller Bearings
Demountable Rims
3 Electric Lights
Speed 45 Miles per hour
Made with 2 and 5 Passenger Bodies

Top and windshield not included in price. We equip this car with mohair top, side curtains and slip cover, windshield, gas tank for headlights, speedometer, self-starter, extra rim and brackets—all for $100 extra (list price $170).

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement.

Comparing the Incomparable

IN the earlier years of the motor truck the relative efficiency of electric and gasoline driven vehicles formed a common topic of discussion. To-day, such partisanship has practically ceased, for it is generally realized that each type has its own distinct sphere of service, and it is useless to pit one against the other when they do not run parallel courses. Generally speaking, the electric truck excels in territories of small radius, while the gasoline truck is pre-eminently adapted for long hauls. There are exceptions to this classification, of course; under certain conditions the gasoline truck can be used to advantage in a small territory, and occasionally very long hauls are made with electric trucks. But as a rule, large users of motor vehicles find it necessary and economical to use both the gasoline and the electric types.

In the present issue of the SCIENTIFIC AMERICAN two motor truck comparisons are published, based on data from different sources, and they appear to be rather discrepant. One confines itself to comparing the motor truck with the horse, while the other goes a step further and compares the gasoline with the electric wagon. At once the question arises, where are the points of contact? The comparison is based on an exceedingly large number of observations made by the Massachusetts Institute of Technology. These observations have been carefully tabulated, and it was found that the only unit common to all is the cost per mile of operation. The estimate of expenses has been very thoroughly summed up. It is distributed under four main heads, namely, the energy source, maintenance, garage or stable, and overhead charges. The investigators realized the difficulty of making their estimate. It was hard to judge the depreciation of a machine in the limited time during which the observations were taken. This could not be based on the work of old machines. The motor truck is still undergoing development and is constantly being improved, and no doubt new machines, although they have not yet shown their work, are longer lived than the older ones. Despite these difficulties the Institute has made a comparison which we have translated into a picture on page 70. The result is startling indeed. It is remarkable that the horse is not so hopelessly outclassed, particularly for light delivery, as we had been led to believe by previous comparisons. For half-ton parcel delivery wagons, the horse-drawn vehicle costs only two cents per mile more than the electric, and it is actually two cents per mile cheaper than the gasoline vehicle. Even with the two-ton vehicle he holds his own, and it is not until it has passed the 5,000-pound mark that the gasoline curve intersects the horse curve. As we proceed toward heavier vehicles, it will be seen that the gasoline truck is gradually creeping up on the electric truck and leaving the horse-drawn truck far behind. In fact, it looks as if the gasoline curve would cross the electric curve somewhere between the six and seven-ton mark.

One important factor we have so far overlooked, namely, the extent of territory covered by the various types of trucks. This is a most important consideration. The Institute tells us that the territory covered in each case is assumed to be within four miles of the loading point. That at once explains the poor showing of the gasoline truck. The gasoline truck has been taken out of its element to compare it with the other two types. Is it not like comparing a Marathon runner with sprinters over a one hundred yard dash?

In Defense of Brain Property

IN the hearings before the Committee on Patents, held to receive the views of inventors and manufacturers on the Oldfield Bill, which seeks among other things to compel a patentee to grant licenses under certain conditions, the fact that the American patent system, since its foundation, has given to the public—as distinguished from the patent owner—greater advantages in profiting from inventions than the public has ever had or ever seriously demanded has been completely overlooked. That the benighted constitution makers one hundred and twenty-five years ago could actually have tucked into that reactionary document a piece of the most up-to-date "public ownership" idea, by fixing a "limited period" for the private ownership of an invention, is a notion still so novel that it is hardly to be wondered at that statesmen who have ceased to read the Constitution should entirely miss it. Labor agitators are loudly demanding that the laborer shall own the thing that he produces. That is exactly what the Constitution granted to the inventor, for the inventor is actually allowed to own for limited periods the thing that he created. Why then reduce to nothing the single successful socialistic property institution in our Government?

The full significance of the reactionary measure that Mr. Oldfield would like to see enacted into law, can be appreciated if we translate the terms of his bill into another language, as it were. If Congress should solemnly determine that if anyone permits his real estate to go unimproved, his houses to remain unoccupied, his horses to stand idle, or his clothing to hang unworn for more than three or four years, then anyone else in the United States may hail him into Federal Court, and by legal proceedings extort the unconditional permission to build on that real estate, to occupy the houses, to use the horses, or to wear the clothing, simply upon paying to the unfortunate owner a sum which the court, after some guessing, deems just," we would have almost an exact parallel to the doctrine that Mr. Oldfield seeks to engraft upon our patent system.

The purpose of the patent laws of the United States seems to have been ignored. What does the public demand? Simply disclosure of the invention and the right to enjoy it unrestrictedly after the lapse of a certain period. If the limited monopoly that the inventor now receives is curtailed in the manner proposed, we may expect to find manufacturers refusing to take out patents and endeavoring to keep their processes secret.

Indeed, even the present patent system is not quite liberal enough for some inventors. Dr. Baekeland testified before the committee that a well known photographic paper that he once manufactured is still made by a secret process, and Mr. H. Ward Leonard, a distinguished electrical engineer and inventor, stated that certain enamelling processes of his were not patented, but were carried out in secret. The inventions of both men are valuable, yet it is doubtful if the public will ever enjoy them in the manner contemplated by the present patent laws. Sir Henry Bessemer, in his fascinating autobiography, tells us that he invented a process for making bronze and gold powders, which process he kept secret, we believe, for a number of years. Out of that secret process he made the fortune which afterward enabled him to engage in the costly experiments that eventually gave the world Bessemer steel. If the English patent laws had been somewhat more liberally framed, Bessemer would not have been allowed to enjoy a monopoly which unquestionably deprived the public of a great right.

The Block Signal and Control Board

IN view of the present widespread public interest in the subject of safe railroad travel, we direct attention to the fourth annual report of the Block Signal and Train Control Board, a document which should be in the hands of every one who is giving or about to give practical attention to this matter. Copies can be obtained either gratuitously or at a very small price on application to the Superintendent of Public Documents at Washington. The report not only gives a *résumé* of what has been done in the way of either encouraging or compelling the railroads to install safety appliances, but (and this is perhaps even more important and illuminating) it outlines the proper attitude of the Government to the railroads in the matter of compulsory legislation, and sounds a timely note of warning as to the inadvisability of hasty legislation, that is to say, of legislation which runs ahead of the actual state of the art, particularly as regards the question of automatic train stops.

Let it not be supposed from what we have said above that the claim of the railroad officials made at the recent investigation of the Westport disaster in this city that there was no practicable train stop in existence, is warranted by the facts. For several years past the Board has been carrying on exhaustive tests on automatic stops which in its judgment gave promise of being of practical value. Speaking of these tests, the report says: "The information obtained from tests, together with knowledge of the general state of development of the art of automatic train control, leads the Board to conclude that there are several types of apparatus and methods of application which, if put into use by the railroads, would quickly develop to a degree of efficiency adequate to meet all reasonable demands." Yet the Board is perfectly fair to the railroads, for it says that it does not wish to be understood that the conditions of entirely acceptable automatic train control as formulated by it in the ten characteristics published in its report (see page 67 of this issue) are fully met by any one of the devices it has thus far examined. In the opinion of the Board the art of automatic train control is "still largely in the experimental stage," but it considers that it is far enough advanced to warrant the installation of available devices with a view to their further development to meet the demand for safety in train operation.

It is well understood by those of us who keep in touch with railroad matters that, hitherto, the railroads have not only failed to show any disposition to encourage the invention and development of the automatic stop, but that they have been, in most cases, strongly averse to it. This opposition certainly cannot be due to a belief that the production of a satisfactory device of this character is mechanically impossible; for the mechanical or electrical elements involved are not materially different from those used by the railroads in the every-day operation of their interlocking and block signals, train brakes, and other devices. The average railroad management is desirous of getting the largest amount of traffic possible over its lines in the shortest possible time, and, incidentally, of doing this with the least amount of risk either to rolling stock or passengers and employees. But unfortunately there is a tendency to slight the second consideration in favor of the first. Certainly the cry of "safety first" has not been the ruling principle in railroad operation, and the Board is perfectly justified in its opinion that "the question of the actual design and construction of the apparatus necessary for automatic train control system has not been as great an obstacle in the way of its adoption as the operating question involved in its use."

The independent inventor working outside of the railroads, has done his part and done it well in producing several promising designs for automatic train control on steam railroads. The automatic stop has been proved to be a thoroughly practical device under the exceptionally dense traffic of the New York subway, where so far from limiting, it has greatly increased the number of trains that can be run over a given length of track in a given time with safety. The Block Signal and Train Control Board has shown, by test, that there are stops suitable for steam railroads which in its opinion if installed and actively developed by the railroads themselves, would soon be brought to a point at which they would satisfy all requirements of daily operation. Furthermore there is just now great activity, expert and otherwise, being shown in this field, and undoubtedly additional devices will be forthcoming for test by the Train Control Board.

It is evident that the question has reached the point where it is distinctly "up to" the railroads, and upon their attitude alone will depend the question of compulsory legislation by the Federal Government. It is certain that the railroads do not want compulsory legislation, and it is equally certain that they can prevent it only by a change of attitude and a sincere and earnest co-operation in meeting the unmistakable demand of the traveling public. The Board does not believe that at the present time legislative compulsion would be wise, but it does believe that the railroads should be urged and expected to develop the art of automatic train control, so as to provide devices which will meet their operating conditions. "This," says the report, "appears to the Board to be entirely practicable, *and should it not be done with a reasonable degree of expedition, steps should be taken by the Government to stimulate such action.*"

The case could not be more fairly stated. Let us hope that this may prove to be that word to the wise which is sufficient.

Agriculture in the Congo.—Since the Belgian government has been carrying out active operations in the Congo region, one of the interesting features is the agricultural work which is being carried on there, and especially the attractive botanical garden and establishment located at Eala where observations are made upon the native plants. The area now in use is about 500 acres, of which 200 acres are devoted to the botanical garden proper. The personnel consists of 8 specialists including an entomologist and a chemist, with 500 natives engaged on the premises. An annual fund of $30,000 is allowed.

Engineering

Installing Spillway Sluice Gates.—Several of the fourteen sluice gates required in the Gatun spillway have been put in position. These gates are massive structures of steel, 19 feet high by 47 feet 10¼ inches in length, each weighing 44 tons. They will slide vertically in steel grooves formed in the concrete piers which have been built above the crest of the spillway dam, and they will serve to regulate the height of Gatun Lake.

New York Erects Twelve Thousand Buildings.—During the past year some twelve thousand structures of various kinds were erected in New York Were they all dwellings for single families, the sum of $207,000,000 expended would furnish sufficient homes for a city of about 60,000 people. In Manhattan the sum of over $116,000,000 was invested in the construction of buildings. During the year, over $30,000,000 was expended on office buildings alone

Diesel Marine Engines of 24,000 Horse-power—It is authoritatively stated that the German navy is having constructed a twin-screw Diesel marine engine, which will consist of two sets of six-cylinder, double-acting engines, each set giving 12,000 horse-power, or 2,000 horse-power per cylinder To those who have closely followed developments, this information will cause no surprise, for the Germans have been making wonderful strides in the construction of oil engines of large size.

New Gyroscopic Compass a Success.—A board of naval officers appointed to test the new gyroscopic compass, which was installed experimentally on the destroyer "Worden," have found it to be remarkably free from oscillation due to the rolling and pitching of the vessel. Experiments which have been made with the same compass aboard a submarine show that it enables a helmsman to steer a more accurate course when the vessel is submerged

Turkey Sells Her Dreadnoughts.—All work has been stopped by Vickers, Ltd., of Barrow, on the construction of the Turkish dreadnought "Mahmed Reshad V" The vessel will probably be completed for some other power A sister ship under construction by Armstrong will also find its way into some other navy The Turkish cruiser "Drama," of 3,800 tons, has been sold to Italy for $1,000,000 There is no difficulty, in these days of feverish naval activity, in finding a ready market for warships

A 10,000 Horse-power Transmission Gear—A test has recently been made at the Vulcan Works, Hamburg, of a Föttinger hydraulic transmission gear of the great capacity of 10,000 horse-power This is one of two transmission gears which are to be fitted on a new German liner The plant underwent a continuous trial of two weeks' duration, night and day, under high load The turbine shaft is designed to run at 850 revolutions per minute and the secondary or propeller shaft at 170 revolutions. The transmitter ran smoothly without noise or vibration, reversing took place rapidly, and the efficiency obtained was close upon 90 per cent.

A Sun-power Plant in Egypt.—At Meadi, a suburb of Cairo, is a sun-power plant of unusual interest. It consists of five reflectors, each 204 feet long, whose cross-section is in the form of a parabola, with the generator units at the focus. The last-named are of zinc, built of rectangular sections 14 inches wide. To render them efficient, they are painted with a black paint of high heat-absorbing capacity The water is introduced at the lower end and the generator at its upper end is provided with a steam connection 4 inches in diameter The reflectors are lined with silvered glass mirrors. The plant works best at a pressure slightly below the atmosphere.

The New Quebec Bridge—The revised design for the Quebec bridge is so far advanced that details of the principal members are available. The main span is 1,800 feet long. The top chord members of the cantilevers will consist of double lines of 16-inch I-bars. The bottom chords will have the enormous dimensions of 7 feet height by 10 feet width The length from panel point to panel point will be 86 feet, each full panel of the bottom chord for one truss will weigh 200 tons. Each cast iron base for the towers will weigh 500 tons. The stringers reaching from panel point to panel point are massive plate girders 10 feet in depth, each weighing about 60 tons.

The Essential Feature of the Diesel Engine.—In the course of a paper recently read by him at Berlin, Dr Diesel denied that the essential feature of the Diesel process was the auto-ignition of the fuel. He stated that motors in which the auto-ignition of the fuel took place were in use before the Diesel process came into being, indeed, he had never laid a claim to auto-ignition in any of his patents. What he was aiming at was a process in which heat was utilized to the highest possible extent, and auto-ignition became embodied in the process incidentally during the evolution of the design. "The height of compression," said Dr. Diesel, "was not determined by the ignition limits of the fuel, but solely by the endeavor to obtain the highest possible figure for economical fuel utilization."

Electricity

Wireless Telegraph Station at the Vatican.—It is stated that a private wireless telegraph post is to be installed in the Vatican which will transmit to a considerable distance, and the Marconi wireless company has already furnished the first part of the apparatus The antenna will be set up in the gardens of the Vatican

Rathenau Medal Awarded to Edison.—On the evening of January 23rd at the American Museum of Safety, the Rathenau medal for the best electrical process or device for safeguarding life and health will be awarded to Thomas A Edison He will be the first American to obtain the prize It will be presented to him because of his storage battery, which provides a safe power supply for use in mines, submarine boats, and factories where explosives are made

Increase in the Use of Wireless Telegraphy—The annual report of the British Postmaster-General states that wireless telegraph messages sent to and from ships have increased 11.8 per cent beyond the previous year The increase is partly due to the larger number of vessels now equipped with "wireless" and partly to a reduction of tariff for vessels making short voyages. Nearly all of the wireless stations in Great Britain are now in the hands of the Post Office, the only private commercial stations being the Marconi stations at Clifden and Poldhu

Twenty-seven Years' Progress in Incandescent Lighting—An English electrical magazine publishes an interesting diagram showing the progressive reductions in the cost of the incandescent electric light which have taken place since 1885 The improvement has been twofold in the increasing efficiency and life of the lamp and in the reduction in the cost of current. It is probably not realized by the average consumer of electricity that whereas the first carbon filament lamps, supplied with energy at about 25 cents per unit and consuming 5 watts per (British) candle-power, gave only 200 candle-hours for 25 cents, with the best type of drawn-wire tungsten filament lamp to-day, supplied with energy at 8 cents per unit and consuming 1¼ watts per candle-power, the same sum of money gives 2 400 candle-hours

Replacing Reciprocating Engine-driven Generators by Turbine Units in England—In one of the generating stations of London it is proposed to "scrap" engines and generators only ten years old, and of 14 000 kilowatts aggregate capacity, because the present output of the station is insufficient to meet the demands of the tramways supplied from this station By replacing four reciprocating engine units of 1,500 kilowatts capacity each by four 8,000-kilowatt steam turbine-generators, the maximum output will be largely increased Two of the old sets will be changed at a time and it is estimated that the saving in coal will be over $57,000 for the first two turbines, which more than offsets the debt charges incurred by the change

A New Direct-current Steam Turbine-generator—The generation of direct-current electrical energy by the steam turbine-generator has been a problem on account of commutator difficulties at the high rotating speed at which the steam turbine should run in order to show a steam economy comparing favorably with the reciprocating engine. In the effort to solve this problem so-called "unipolar" steam turbine-generators having a highly simplified current-collecting device, and reduction gearing between the steam turbine shaft and the electric generator shaft, have been tried A new scheme for direct-current generation is now announced in the form of an alternating-current induction generator combined in one machine with a rotary converter In this "turbine converter" one member of the generator is mounted on the converter shaft and the other member (usually a squirrel-cage rotor) on the turbine shaft with the revolving field of the generator arranged to rotate the same way as the converter armature, giving a net generator speed equal to only a fraction of the turbine speed In a set of 500 to 600 kilowatts capacity the full-load efficiency is stated to be 94 per cent

Magnifying Feeble Signaling Currents.—Two interesting types of relay for submarine cable work, designed to improve on the "siphon recorder" invented by Lord Kelvin in 1867, were described at a recent exhibition of electrical apparatus in London The problem of high speed working is to cause very feeble transient currents to make distinct records. In one of the new devices the object is attained by mechanical means. The suspended coil of the relay has two silk fibers running to and around a rotating spindle. The slight movement of the coil in either direction, by slightly increasing the friction of one or the other of the fibers on the rotating spindle, causes the latter to supply a supplementary force many times greater than that exerted by the coil itself The other device virtually magnifies the feeble arriving current by thermo-electric means. The suspended coil carries an arm at the end of which are two tiny thermo-electric couples forming a T between two little alcohol flames. The slight movement of the coil, by turning one or the other of the thermo couples toward one flame and away from the other, generates a current in the one direction or the other 27 times greater than the received current.

Science

A Swiss National Park.—A magnificent national park, the largest in Europe, is about to be established in the canton of Grisons, Switzerland It will ultimately have an area of nearly 80 square miles, all of which will be wholly withdrawn from human interference and set aside as a biological preserve

Changes in the Map of Greenland—A series of maps presenting the results of the surveys carried out by the ill-starred Mylius Erichsen expedition of 1906–08 to northeastern Greenland has been published in the *Geografisk Tidskrift* These show that Greenland extends much farther east than was formerly supposed, and add about 150 000 square miles to its area.

Amundsen's Proposed North Polar Journey has been postponed for a year, at the suggestion of the Norwegian government, seconded by Prof Nansen, in order to give the staff more time for thorough training in oceanography, the subject to which the expedition will devote principal attention Captain Amundsen is to be presented with a gold medal for his discovery of the South Pole, at the annual banquet of the National Geographic Society, in Washington January 11th

A Princely Bequest to Science—The will of Albert Samson, who died recently in Brussels, bequeathed the bulk of a large estate for scientific researches Two endowments are created, one under the control of the Royal Prussian Academy of Sciences the other to the Royal Academy of Sciences at Munich The Prussian endowment is worth $500,000, the Bavarian $100,000 The Berlin endowment is to carry out scientific researches into individual as well as social ethics The endowment for the Munich Academy has a similar purpose

French Expedition to Morocco.—The Geographical Society of Paris, aided by the French Academy of Sciences, the National Museum of Natural History and a number of banking institutions, has organized an expedition which will carry on elaborate scientific explorations in Morocco for four or five years, and perhaps longer The party is made up of well-known specialists in several fields, including M Gentil who will have charge of geology and mineralogy, M Baugnil in charge of agronomy, M Pallary, zoology, and Prof Pitard, botany

An Institute to Study Fuels.—Under the auspices of the Kaiser Wilhelm Scientific Society there has been founded an institute for research upon combustibles The buildings of the institution are to cost $150 000, and the State allows an annual endowment of $30,000 Another endowment coming from the mining syndicate of Westphalia and the Rhine amounts to $25 000 and the above-mentioned society itself contributed the sum of $5 000 It is stated that the buildings of the institution will be opened for use early in 1914 and the director is to be Prof F Fischer, of the Berlin Hochschule

Changes in the Weather Bureau The River and Flood Division of the Weather Bureau, which has charge of the important work of stream-gaging and river-stage prediction, has been placed under the direction of Prof A J Henry, lately in charge of the Mount Weather Observatory He is succeeded at the latter institution by Dr W R. Blair Three officials of the Bureau have recently been promoted to the grade of professor of meteorology, viz, Dr O L Fassig the well-known climatologist, now in charge of the station at Baltimore, J Warren Smith, a specialist in agricultural meteorology, who is stationed at Columbus O, and W M Wilson, stationed at Ithaca, N Y C Fitzhugh Talman librarian and supervising examiner of the Bureau and W R. Blair, of the Mount Weather Observatory have been appointed junior professors, a new grade in the service.

The Sphygmomanometer is an instrument of recent invention for measuring the blood pressure The name is derived from *sphygmos*, the pulse, *manos*, thin rare, and *meter* a measure The manometer had been in use for some time as an instrument for measuring the tension of gases and vapors, and was readily adapted to testing blood pressure by adding a rubber bulb and a cuff with rubber bag attached on the inside This is placed over the brachial artery, above the elbow, and when the pressure through the rubber bulb has shut off the artery so the pulse cannot be felt at the wrist, the reading in the graded scale at the height of the column of mercury indicates the blood pressure The normal blood pressure is 125 millimeters In hardening of the arteries, and accompanying heart and kidney complications, the blood pressure is an important symptom to be studied Several of the large life insurance companies require the blood pressure to be taken in applications for large amounts One company requires it in all applicants without regard to age or amount This company claims to have saved $50 000 in losses the first year in which they required the use of the sphygmomanometer They followed the history of cases rejected on account of high blood pressure only, and found several who died within the year of apoplexy.

Moving and Talking Pictures

MOTION pictures are at the present time usually exhibited by optical projection, enlarged images of pictures carried by a long strip of film being thrown upon a screen or curtain. This process is to a large extent the reverse of that employed in taking the pictures, to effect which reduced images of the scene which is to be reproduced are allowed to fall in succession upon a sensitized film. In the apparatus commonly employed for obtaining the pictures snap-shots are taken at the rate of sixteen per second upon the film which is intermittently moved. A rotating shutter provided with an opening allows sixteen images per second to fall in succession upon the film. The apparatus is so constructed that the film is held stationary while each picture is taken and then is moved forward at a high rate of speed into proper position for the next picture, this movement occurring at the time when the shutter is so positioned as to protect the film from the light. The film carrying the exposures is developed, and from the negatives thus obtained prints are made upon a similar strip of film for use in the projection apparatus. This apparatus is usually similar to the camera except that a powerful light is provided to throw successive images of the pictures upon a screen. These images are enlarged by means of an objective lens, and appear upon the screen in such rapid succession that before one picture has time to fade from the retina of the eye another one is in view. Since each picture is slightly different from the preceding one and since the pictures blend imperceptibly into each other, the illusion of movement is produced, and the observer sees the original scene re-enacted.

On August 24th, 1891, Thomas A. Edison filed two applications for patents, one of which became patent number 493,426, dated March 14th 1893, and, therefore expired on March 14th, 1910. The apparatus disclosed in this patent involves a cabinet having a sight opening across which the picture film is continuously moved, each picture being momentarily illuminated when it is accurately centered with relation to the sight opening. This device is not adapted to project pictures and provides for only one observer at a time. A device of this character was for a time in extensive use, but it has now been largely replaced by the projector. The other application referred to matured into patent number 589,168 on August 31st, 1897, and consequently does not, or rather the reissues which have superseded it do not expire until August 31st, 1914. The device covered by this patent is intended only for taking pictures, but is, however illustrative to a large extent of the principle both of the camera and the projector commonly used. The apparatus is shown in Figs. 1 and 2. The film 3 passes the lens tube on its way from the reel 1 to the reel 2, being drawn along by two feed wheels 5, the teeth of which engage perforations placed along each side of the film. The film would move continuously were it not that the rotation of the feed wheels is periodically checked by the interaction of two toothed wheels, the one 25 mounted on the main shaft 26 and the other 23 on the feed wheel shaft 6. One tooth of the wheel 23 is allowed to escape at a time, and thus the film is intermittently advanced. Mounted on the shaft 26 to rotate between the film and the lens tube is a disk 11, which is apertured to permit the light rays to fall upon the film each time the latter stops.

Although present machines differ from this machine yet certain features have been used in various machines. This patent has, therefore, been made the basis for litigation. The Court of Appeals of the Second Circuit (114 F R., 926) held claims 1, 2, 3 and 5 of this patent invalid on account of being broader than the state of the art warranted. Claim 1 covered the combination of three elements (1) any means capable of intermittently projecting at such rapid rate as to result in persistence of vision images of successive positions of the object or objects in motion as observed from a fixed and single point of view, (2) a sensitized tape-like film, (3) any means for so moving the film as to cause the successive images to be received thereon separately and in single line sequence. The scope of the second claim was the same except that it was limited to a single camera with a single lens. The third claim differed from the second only in that it was restricted to intermittent motion of the film and exposure of the film during the periods of rest. The court based their decision on the following four references. The French patent to Ducos of 1864 describes a camera having a large number of lenses caused to act in rapid succession upon a series of sensitized plates or a surface of sensitized paper. The lenses and the sensitized surface move continuously at the same rate of speed while the picture is taken, one lens after another passing an aperture which admits light. The images are formed from the same point of view—the single aperture. U. S. patent to Le Prince, 376,247, January 10th, 1888, discloses a camera provided with a battery of sixteen lenses which act upon two strips of sensitized film placed side by side. The lenses are provided with shutters, eight of which facing one film are operated in rapid succession. The eight facing the other film are then operated, during which time the first film is moved into position to receive another eight exposures and so on. Unlike the Ducos camera, the lenses in this device are fixed and, therefore, the pictures are not all taken from the same point of view. The photographic gun of M. Marey, described in the SCIENTIFIC AMERICAN SUPPLEMENT of June 10th, 1882, discloses a single lens camera which takes twelve pictures in a circular series around a sensitized plate rotated behind a slit which allows entrance of light. The plate is rotated intermittently by clock work arranged to give one rotation with twelve periods of rest. The number of exposures for one operation is limited to twelve. Mr. Levinson in the *Brooklyn Eagle* of June 14th, 1888, described a camera for taking motion pictures in which a single lens is employed to obtain images on plates carried by an intermittently operated wheel, each plate being exposed while at rest. He stated further that the mechanism employed to drive the plate carried could be employed to operate a continuous strip of paper or a film carrier. The court held that in view of these references the invention of Mr. Edison was not in such sense a primary one as to authorize the claims on which suit was brought. In regard to the prior art they stated in particular that he was anticipated by Marey in an apparatus capable of producing negatives and embodying means for passing a sensitized surface across a single lens camera at a high rate of speed and with intermittent motion and for exposing successive portions of the surface during periods of rest. The fifth claim of the patent, which was for a film having the photographs thereon was also held invalid in view of the references. Claim four of the patent was not included in the suit and was not passed upon by the court in this decision.

After the patent had been adversely passed upon it was reissued in two parts. Reissue No. 12,037 for the camera and reissue No. 12,038 for the film. The reissue for the camera contained four claims, the first three being more limited than those in the original, while claim 4 was the same as claim 4 of the original. Claim 1 contained four elements (1) a single stationary lens, (2) a single sensitized tape-film supported on opposite sides of and longitudinally movable with respect to the lens, and having an intermediate section crossing the lens, (3) feeding devices engaging such intermediate section of the film and moving the same across the lens of the camera at a high rate of speed and with an intermittent motion, (4) a shutter exposing successive portions of the film during the periods of rest. Claim 2 also included a continuously rotating driving shaft, by which the feeding devices and the shutter were operated. It limited the shutter to a continuously rotating shutter. Claim 3 differed from claim 2 in omitting reference to the shutter as being continuously rotating and operated by the shaft, and included a reel for winding

A Successful Automatic Train-stop

A Device Which Saves the Train, Reports Disregard of Signals, and Thereby Stiffens Discipline

IN the fourth annual report of the Block Signal and Train Control Board to the Interstate Commerce Commission in December, 1911, there occurs this paragraph "The Board has no hesitancy in saying that, had the railroads directed the same efforts toward the development of automatic train-control apparatus that has been devoted to the development of interlocking and block-signalling apparatus, we should now have adequate installation of automatic train-control devices, which would permit an engineman to handle his train without interference as long as he did it properly, but would intervene to stop his train if he disregarded a stop signal or ran at excess speed, where speed restrictions were prescribed."

During the past fifteen years the SCIENTIFIC AMERICAN has repeatedly drawn attention to the growing number of fatalities and injuries on our railroads, and for many years we have urged the use of the automatic train stop as a salutary check upon disobedience of signals and a most effective safeguard of the lives of passengers. Unfortunately, the railroad companies, for various reasons, have been opposed to the train stop, and with a few exceptions it is only recently that they have begun to give it unwilling attention. A few roads, operating under special conditions, have installed the stop, and in such cases, particularly on the New York subway, it has proved to be a brilliant success. To-day some roads are testing out devices of this kind that have been developed on the outside, and one railroad has recently made the offer of a reward, the conditions of which will be found on the correspondence page of this issue in which it solicits the assistance of the outside public in the solution of the problem

The success of the mechanical trip train stop, as used on the New York subway where, during several years of operation on express trains under a headway of one minute and 43 seconds, there has been only one failure out of 277 846 movements, proves that, when it is installed in subways or under conditions such as those on the Boston elevated road, where it is not subject to attack by snow and ice, this type of stop is thoroughly reliable.

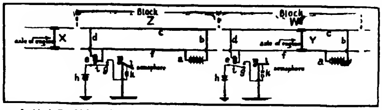
For use in the open on steam railroads, however, where the mechanism both at the rail and on the train will be subject to destruction or disarrangement by snow and ice, or by trespassers on the tracks or intentional train wreckers, the problem is more difficult and modifications become necessary In all probability it will be found that the most satisfactory system is one which operates electrically upon what is known as the "closed circuit" system, and dispenses altogether with projecting mechanical parts which are liable to be injured or entirely carried away in the stress of day by-day railroad operation. Also, it may be taken for granted that the successful, electrically-operated device must form part of or co-act with the track circuits which operate the standard block signals as installed on our railroads.

It is necessary that anyone who undertakes to solve this problem should have a clear understanding of the operation of the electrically-controlled automatic block signal system To this end we have prepared the accompanying diagramatic view showing its basic features, which consists of a track battery a furnishing a low voltage electric current through wire b, to one line of track rails c at the end of a block Z, which is isolated by means of insulated joints from the adjoining blocks, a wire connection d to a relay e, which is energized by the current as thus supplied and the other line of track rails f closing the return circuit to track battery a The relay being thus energized, attracts the armature i and makes the contact g This permits current to flow from a signal battery or other source of power h to the signal magnet or motor k, which holds down the semaphore l against the action of the counterbalance m, which normally holds the semaphore in the horizontal or stop position A train X approaching block Z, observes that the semaphore is in the downwardly inclined position and has the right to proceed into the block Z

If a train Y occupies block W, the front axle of the train short-circuits the track current, the relay is de-energized, and it no longer holds the armature against the contact. Thereupon the signal magnet or motor, as the case may be, is deprived of current and the counterbalance weight m automatically draws the semaphore into the horizontal or stop position warning the approaching train that the block is occupied A broken rail interrupting the flow of current in the track circuit or any defect in the apparatus that breaks the circuit, de-energized the signal magnet or motor k and allows the semaphore to go to the stop position.

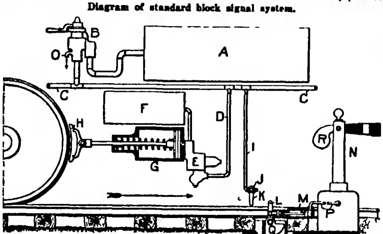
This method of controlling the signals is known as the "closed circuit" principle It is essential in the safe operation of a system which must err on the side of safety should anything go wrong Every successful automatic stop must be arranged on this same closed-circuit principle, it must be included in the circuits which control the block signals, its movements to clear or stop must be coincident with those of the signals, and any failure of the circuits or mechanism must cause it to be drawn by gravity to the stop or danger position

Now the same broad principle is followed in the automatic airbrake (see diagram) The main reservoir A on the engine, the train pipe C which runs the full length of the train the auxiliary air reservoirs F on each car are normally maintained under full air pressure When the engineer opens the brake valve B the pressure in the train pipe C and branch



In block Z, which is clear track battery a through circuit b c d f relay e contact g and signal battery h, causes magnet k to lower semaphore l In block W engine axle Y short-circuits track-current l is released and raised by counterweight m to stop position.

Diagram of standard block signal system.



A, main reservoir B, engineer's brake valve C, train pipe. D, branch pipe E, triple valve F, auxiliary reservoir G brake cylinder H, brake shoe I, trip branch pipe. J, trip valve K, trip valve lever L trip M trip piston N signal O, exhaust from train pipe P, air pipes. Q, stop counterweight R signal counterweight

Relation of automatic signal and stop to train brakes.

Home and distant signals clear, stop lowered.

Stop raised opens valve on pipe and sets brakes.

Counterweight in box raises stop when signal is at danger.

AUTOMATIC SIGNALS AND STOP AS USED IN NEW YORK SUBWAY.

pipe D is reduced, and this causes the triple valve E to admit air from the reservoir F to the brake cylinder G on each car, thereby setting the brakes. Any failure of the air pressure, as in case of a train breaking in two causes the brakes to be automatically set. For automatic stop setting of the brakes, a trip branch pipe I is led down from the train pipe and terminates in a trip valve J provided with a trip lever K, which is so placed that it will engage with a trip L, when the latter is in the raised or stop position.

The mechanical trip as installed in the New York subway and elsewhere is shown in the diagram and in the three photographic views. It consists of a short lever placed adjacent to the track rail, which is normally held down clear of the trip valve lever K by the compressed air piston M. The valves admitting compressed air to the back of this piston and to the piston operating the signal N are controlled by electro-magnets in the signal circuit, as described above. Normally, the trip, like the signal, is maintained in the clear position but when the block is occupied, the air pressure back of M is released and the trip rises to the stop position under the action of the counterweight Q.

Now it is evident that the weak point, if there is one, in this system is the possibility of a failure of the trip to register with the trip valve lever, either through one or the other being broken entirely off or twisted, or through their movements being obstructed. In the New York subway or on the elevated, this possibility is very remote but in the open on steam rail roads, especially during the winter months, it might well happen. If there were such disarrangement, the engineman would be unaware of it. Herein lies considerable peril, and it is for this reason, among others, that railroads operating in the open have been opposed to the mechanical stop. To quote one of the leading railroad engineers in the country "If an automatic stop is to be generally employed on American railroads, it must be certain in its action, and this means that it must be constructed on the closed-circuit principle, a failure in the co-ordination in the parts of which must be just as certain to stop the train as a fractured rail or a defect in the apparatus will bring about a stop indication of the signal semaphore"

In the presence of this dilemma, the thoughts of inventors have naturally turned to electricity and the substitution of electrical contacts for mechanical stops. One system the Lacroix, using a third rail contact and a closed electrical circuit in the cab, after undergoing a series of tests by the Block Signal and Train Control Board, received the following endorsement "The test indicated that the apparatus could be expected to operate satisfactorily under severe weather conditions. The system with reasonable inspection and maintenance would be safe, reliable, and its use would tend materially to promote safety of operation on a railroad using it" We quote this case to show how entirely without justification is the contention of the steam railroads that there is no automatic stop in existence or in sight, that will meet the severe requirements of daily out of doors operation.

Admitting as essential to a successful stop the principle that the whole apparatus—track circuit, engine circuit and the contact relations between the two—must be upon the closed-circuit principle, detecting its own failures and incapable of giving a false "clear signal," this problem becomes a most interesting and attractive one, capable of a wide range of variation in its solution The automatic train stop has come to stay Its necessity is becoming increasingly realized, and it is to be hoped that the railroads generally will change from an obstructive to a favorable attitude, and that the train stop will be adopted voluntarily and widely and without any resort to Federal legislation.

The Death of Dr. Lewis Swift

ON January 5th Dr Lewis Swift, one of the great astronomical observers of our time, died at Marathon N Y at the ripe age of ninety two. He was chiefly noted for his work on nebulæ, of which he discovered 1,240 his studies of comets of which he discovered 14, his investigations of shooting stars, solar eclipses and possible intramercurial planets. It is said that his first interest in astronomy was aroused by reading Dr Dick's books at a time when he was in business. He made his reputation with the discovery in 1862 of the great comet that bears his name, a discovery that resulted in his removal from Hunt's Corners to Rochester There, on the roof of a cider mill he set up an humble observatory where he discovered comet after comet and nebula after nebula Much of this work was done while he was in business in Rochester

Blackening Tan Leather

TO blacken tan leather it should be first rubbed with a ten per cent solution of tannic acid. Let this solution dry thoroughly, when a ten per cent solution of iron sulphate should be applied. This gives an intense black, is easily applied and is harmless to the operator

Teams and Motor Trucks Compared

By H. W. Perry

THE front page illustration tells its own story so plainly that it is almost unnecessary to amplify it. Some of the advantages of the motor truck over the team drawn wagon may be thus summarized

The average distance covered per day by a two-horse team varies between 16 and 20 miles, whereas the average distance covered per day by a three or five-ton motor truck varies between 40 and 60 miles. Horses and wagons could serve daily an area of 314 square miles on a ten mile radius, on the other hand motor trucks, operating on a 25-mile radius, would cover 1,963 square miles.

The work done by a two-horse team per day varies from 48 to 60 ton-miles. On the other hand, motor trucks of from three to five-ton capacity perform an amount of work measured by 165 to 225 ton-miles per day

At \$8.50 per day, the cost per ton-mile of hauling by team is 17 7 to 14.16 cents, but the cost per ton mile of hauling by three or five-ton motor trucks at \$12.25 to \$15.60 per day is 7 42 to 6.88 cents.

Equally remarkable is the amount of space occupied by the horse-drawn truck as compared with the motor truck. A team and wagon is about 26 feet long, a three to five-ton motor truck, 20 feet long, a four-horse team and wagon is about 39 feet long, and a ten ton motor truck, its horse-drawn equivalent, only 25 feet long. So far as areas are concerned an ordinary team and wagon will occupy 182 square feet, but a three to five-ton motor truck only 140 square feet.

In the matter of storage space required for gasoline and feed the motor truck engine displays an advantage. An amount of hay and oats sufficient to feed a team for one month occupies a volume of 100 cubic feet, but the gasoline required for a motor truck for one month will occupy only twenty cubic feet. The cost of hauling by motor truck is incomparably cheaper than by horse and wagon. Thus, the cost of hauling 1,000 tons ten miles by horse and wagon is \$160, but only \$70 by motor truck

The amount of work performed by one motor wagon is equivalent to the amount of work performed by three and one half average teams. To haul 585,000 tons an average distance of one mile in a year, would require 100 teams, but 39 motor trucks would theoretically be required to haul the same load an average distance of one mile in a year

The cost of keeping and using 39 teams and wagons per year would be \$99,450, but the cost of keeping and using ten motor trucks would be only \$42,000.

Judging by the registration of horse-drawn wagons in Chicago, the use of horse-vehicles is decreasing at the rate of 15.8 per cent per annum. In other words 68,000 horse-drawn wagons were registered in Chicago in May, 1911, and only 53,600 in September, 1912. On the other hand the use of motor trucks is increasing at the rate of 120 per cent a year, this estimate being also based on Chicago statistics. It seems that the number of motor wagons registered in Chicago in May, 1911, was 800, and the number in September, 1912, 2,094.

Brontidi

IN this week's SCIENTIFIC AMERICAN SUPPLEMENT Mr. C. Fitzhugh Talman gives an account of some curious acoustic phenomena which have been generally called "brontidi," "mistpoeffers," or "Barisal guns," but which bear scores of other names in various parts of the world. They take the form of muffled detonations, resembling the sound of distant cannon or peals of thunder, and are heard chiefly in warm, clear weather

The first systematic investigations of these phenomena were made in India. The fact that they were frequently reported from the neighborhood of Barisal, a town in the Ganges delta, led to their being called "Barisal guns," under which name they were first made known to European science at the meeting of the British Association in 1890. A few years later they were discussed in an extensive memoir by E. van den Broeck, who had collected numerous reports of their occurrence in Belgium, where they are known as "mistpoeffers" (i. e., "fog-belchings" or "fog-hiccups") The most extensive literature on the subject, however, has come in recent years from Italy, where the sounds appear to be extremely common, though very local in their distributions, they are well known in some localities, but entirely unknown in others not far distant. They are popularly known under a great variety of names in Italy, but since 1904 have been generally called by Italian scientific writers "brontidi"—a conveniently non-committal term formed by Prof. Tito Alippi from two Greek words meaning "like thunder." (This is likely to become the international name, with or without changes in termination to suit the various languages, i. e., "brontides" in English and French) In Australia the noises are called "desert sounds," in Haiti, "gouffre," etc. They have been reported from some parts of the United States, especially California. It is difficult to define their distribution, because, except in places remote from human habitation, they are likely to pass unobserved—being taken by most people for actual discharges of cannon, blastings, explosions, and the like.

When once the attention of the world had been directed to the widespread occurrence of brontidi it was found that there are rather numerous references in early literature to apparently the same phenomena. Thus Lord Bacon speaks of "an extraordinary noise in the sky when there is no thunder"

The latest views as to the origin of brontidi are summed up as follows

"Many suggested explanations that seemed more or less plausible when the problem was viewed as a local one—as in the early discussion of Barisal guns—are invalidated by the wide range of physical conditions under which the phenomenon is now known to occur The trend of recent opinion is toward looking upon the source of brontidi as subterranean in most cases, though perhaps not in all. Movements within the crust of the earth must frequently set up vibrations of such amplitude as to affect the ear, when communicated to the overlying atmosphere. Assuming the focus to be far below the surface, the air would be set in vibration over a wide area, giving the indefiniteness as to the direction of the sound that is commonly noted. Prof W H Hobbs, who has made a painstaking study of the seismic geology of Italy, concludes that the brontidi of that country are due to the slow settlement of orographic blocks, and the consequent production of vibrations within their marginal zones."

Whatever the initial cause of the sound, its audibility appears to depend upon definite acoustic conditions that require further investigation. Alippi believes that in order that the sounds may be heard they must be re-inforced by a peculiar configuration of the ground, above or below the surface, and he attaches special importance to the effect of caverns, which he suggests act as resonance boxes in the production of audible brontidi.

A New Industrial Process for Manufacturing Oxygen

By Our Berlin Correspondent

DR. G KASSNER, professor at Münster University, has designed a new process for the manufacture of oxygen which is based on the Tessié du Motays process but, thanks to the absence of any antagonistic effects, lends itself to a far better industrial application than any chemical method so far suggested. Kassner adds to the alkali manganates used in the Tessié du Motays process an alkali salt of metaplumbic acid, thus increasing enormously the efficiency and constance of the mass. The process comprises two phases characterized by the action of currents of steam and air, respectively During the first phase the alkali given off by dissociation is immediately absorbed by the alkali metaplumbate, thus forming orthoplumbate. Inversely, during the second phase, which is that of regeneration, the alkali absorbed by the metaplumbate is given back to the residual manganese oxide, thus forming alkali manganate. This is how the formation and decomposition of the manganate due to the addition of metaplumbate (which eliminates any disturbing antagonistic effects) takes place in continuous succession, without any appreciable alteration in the composition of the mass.

In opposition to physical processes which only utilize indirectly the heat units given off by the fuel, this chemical process works without any appreciable heat losses. It is carried out in the following manner

After being introduced into a suitable apparatus refractory to heat and insuring a constant temperature, the active mass is, by means of a special fire-place, raised to and kept at the relatively low temperature of reaction of about 400 deg. Cent. A mechanically controlled valve causes separate currents of steam (exhaust steam, etc.) and air to enter this mass, at short intervals of equal duration. By inserting a very short discharging phase between the air and steam phases, any nitrogen left after regeneration in the pores of the mass is eliminated. The oxygen produced during the steam phase is led automatically into a gasometer set apart for this purpose. Moreover, a recovering apparatus serves to transmit any heat units escaping with the nitrogen, to the currents of air and steam entering the apparatus, thus preventing as far as possible any loss of heat. Finally, the process is so designed that the charge can be exchanged readily and easily, without any interruption in service worth speaking of, should it after some considerable time's working show any decline in its output which, however, will only happen exceptionally. As, in fact, the active mass remains constant in quality as well as quantity, it will at most require (after protracted working) a mechanical regeneration, restoring it to its previous porosity.

In view of the relative insensitiveness of the mass to the moisture of hot air, the new process would seem to lend itself for metallurgical applications.

The N. Y., N. H. and Hartford Railway's Automatic-stop Prize

Conditions That Must be Observed in the Competition for the $10,000 Award

THE New York, New Haven and Hartford Railroad Company has offered a reward of ten thousand ($10,000) dollars to whomsoever shall invent, perfect, and submit the best automatic device that will safely arrest trains disregarding fixed signals.

The reward will be paid on the order of the Interstate Commerce Commission, the Railroad Commissioners of Massachusetts, and the Public Utilities Commissioners of Connecticut.

Conditions of Competition.

1 Competitors must submit a typewritten or printed description of their device, describing in full all features wherein the device does or does not conform with the requirements as herein below set forth, in consecutive order

2. Any device which in the judgment of the Signal Engineer of the New Haven Company does not satisfactorily meet the essential requirements, will be rejected and if it is the desire of the competitor to have the device developed further, it will be done at his sole expense

3 Any device appearing, in the judgment of the Signal Engineer to have sufficient merit or promise to justify more extended consideration, the Railroad Company will assist Competitor by contributions of money or use of tracks, or both, in such measure as deemed reasonable

4 Any device after meeting the requirements, must show an efficiency equal to that of the signal system in use on railroads at the present time before same will be accepted.

5 Any device accepted will remain the property of the Competitor or Patentee, subject however to the reservation by the Railroad Company, of a right of use without further payments.

6. Before any device is accepted it must be adopted for general use by either the New York, New Haven & Hartford the Pennsylvania or the New York Central Railroads, within the year 1913, 1914, or 1915

7 The device must also have the approval of the Interstate Commerce Commissioners, the Railroad Commissioners of Massachusetts, and the Public Utilities Commissioners of Connecticut.

8 Those desiring to enter this competition must file their application before July 1st, 1913.

Requirements of Stopping Device.

CHARACTERISTICS AS PUBLISHED BY THE TRAIN CONTROL BOARD OF THE INTERSTATE COMMERCE COMMISSION

1 The apparatus should be so constructed that the removal or failure of any essential part would cause the display of a stop signal, and the application of the train brakes.

If electric circuits are employed they should be so designed that the occurrence of a break, cross, or ground or a failure of the source of energy in any of the circuits, should cause the display of a stop signal and the application of the train brakes.

2 The apparatus should be so designed that it may be used on the open railway on bridges, on elevated structures, in tunnels or subways, and where either steam or electricity is used as a propelling power

3 The apparatus should be so constructed as to conform to recognized standards of clearance of rolling equipment and structures, so that those portions of the apparatus placed on the roadway will not be subject to damage by rolling stock or engines, or those portions placed in the vehicle be damaged by structures permitted to exist on the roadway and at the same time all vehicle parts and roadway parts which may have to come into operative relation with each other should be so designed that proper operative relation will be assured under all conditions of speed weather wear of tracks or vehicles, oscillation, and shock

4 The system should operate under all weather conditions which permit the operation of trains

5 The system should be capable of control by ordinary means used for indicating the condition of the block about to be entered, such as electric track circuit

6 The engine apparatus should be so constructed as to prevent the release of the brakes after the application has been made until the train has been brought to a stop, or obstruction or other condition which caused the application has been removed

7 The system should be so designed that should operating conditions require it, speed control may be used that is, provision made for a train to pass an automatic stop in tripping position without the application of the brakes provided the speed is less than a predetermined number of miles per hour

8 The system should be so designed that when no cause for stopping a train exists, a definite and positive or proceed indication will be given at every point where a stop indication would be given or the brakes applied, when adverse or dangerous conditions exist.

9 The system should provide at least for use under congested traffic for the continuous display of indications rather than for their intermittent display at certain definite points, as of course is necessary with fixed signals.

10 The apparatus should be so constructed and installed that it will not constitute a source of danger to trainmen or other employees, or passengers

In addition to above, the following additional requirements must be met

11 The apparatus should be non inductive so that its application to a railroad where alternating current electricity is used as a propelling power it will not affect same

12 The apparatus should be so constructed that it may be used with either absolute or permissive operation also to cause trains to reduce speed at points where a reduction of speed is deemed advisable for safe operation of trains.

13 The apparatus should be so constructed that it will not be made inoperative by snow ice sleet or freezing conditions.

14 The apparatus should be so constructed that two or more engines may be used with one train or a train may be allowed to assist another train without causing the brakes to be set on the second or following engine when passing a signal which indicated proceed when passed by head of train

15 The apparatus should be so constructed that the automatic stopping device shall be operative only in the normal direction of traffic except in connection with signals governing reverse movements.

16 The apparatus should be so constructed with speed control device that a train may pass an automatic stop in stopping position without brakes being applied provided the speed has been reduced to less than a predetermined number of miles per hour

17 The apparatus should be so constructed that with speed control device applied, brakes can be released by engine or train crew after they have once been set by the stopping device provided speed has been reduced to a predetermined number of miles per hour

18 The apparatus should be so constructed that if found desirable proper apparatus can be provided on the engine to record the number of times the automatic stopping device has been applied to the brakes.

Rusting of Iron

IN some very interesting experiments by two German chemists, E. Liebreich and F. Spitzer, the cause of rust in cases which have seemed especially puzzling has been made very clear—as it was shown beyond question that the rust was caused by the paints themselves. They painted polished steel plates, and in order to distinguish them, numbered them with oil paint. The result was that the rusting took place just under the painted numbers—that is, where the "protective" coating was the thickest.

They went further in the matter, and examined iron business signs and the like. As a rule these were made of sheet iron, first painted with a ground color—mostly white, then the lettering was added, usually in black. Removing the coating, it was shown that the rust was most pronounced under the lettering, in fact in most cases was to be found only there.

This set the investigators to thinking, and they carried out their experiments with several kinds of paint, as follows

White lead.
Zinc white (purest zinc oxide)
Red lead
Iron oxide
White lead and lampblack.
Zinc white and lampblack.

Iron plates were brightly polished and four plates coated with the above paints, in different thicknesses of each, one plate getting but one coat, a second two, a third three, and a fourth four, time for drying being accorded. Then all the plates were subjected for a whole day to the action of the steam from water boiling in an open vessel (that is, under no pressure above that of the atmosphere)

The paint was then dissolved off to show the condition of the plates.

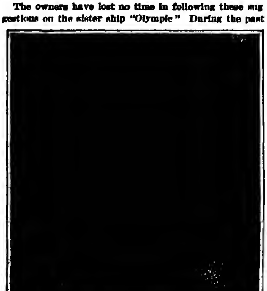
The result was surprising. Under all the single coatings the iron was not at all rusty; under the double coat, partly attacked, under the triple coat, more strongly, and under the four coats, thoroughly rusted!

Apparently one coat—at least of the above-named paints—is better than more. The explanation of this remarkable result would seem to be that the varnish in the second coat dissolves and loosens the first one, making it porous, and that the oftener this process is repeated, the more porous the paint becomes. It would also seem to indicate that one thick coat, if allowed to harden, would be better than several thin ones—which has not been considered to be the case. There seem to be no experiments in this particular on record.

Reconstruction of the "Olympic"

IT will be remembered that the investigations of the loss of the "Titanic," led to the widely-accepted conclusion that, although the construction of the ship was of the highest character as to material and workmanship, she was deficient in underwater protection It was recommended, both by the Senate Committee which investigated the disaster and by the Board of Inquiry under Lord Mersey, that certain structural changes should be made, chiefly below the waterline which would render ships of a design similar to the "Titanic" safe, if not against foundering under any conditions, at least against their foundering under a collision as serious as that which sank the great ship. The most important recommendation was that future ships should carry an inner skin, either in the form of plating on the inside of the main frames of the vessel, or in the form of longitudinal watertight bulkheads, built several feet inboard, which would form the inner walls of the bunkers and extend throughout the boiler spaces.

The owners have lost no time in following these suggestions on the sister ship "Olympic" During the past winter the "Olympic" has been withdrawn from service and extensive reconstructions have been made at the Belfast yards. The principal change has been the carrying of the plating of the double bottom up the sides of the ship, as far as deck F Below the lower deck, the inner skin, as thus riveted upon the frames, will be about 2 feet 6 inches distant from the outer skin of the ship Between the lower deck and deck F the skin will be about three feet inboard



By courtesy of [illegible]
Sketch showing how the floor-plating of the "Olympic" was carried up the sides of the ship to form an inner skin
Increasing the underwater protection of the "Olympic."

The importance of these changes will be readily appreciated and the nature of the construction understood, by reference to the accompanying sketch which shows conditions in the ship as originally built and as they will be when the inner plating has been completed. Formerly a rupture of the outer skin admitted water entirely across the ship. In the future a rupture of this outer skin, unless the penetration were very deep, would admit the water only to the cellular space between the two skins.

Another improvement, which will add greatly to the safety of the ship, is that additional watertight bulkheads have been constructed fore and aft of the boiler spaces, some of which have been carried up to B deck forty feet above the waterline The White Star Company is to be congratulated upon the promptness with which it has recognized the lesson of the loss of the "Titanic" and taken steps to thoroughly insure her sister ship against any such disaster

Artificial Sponges of Paper

WHEN paper pulp is treated with zinc chloride there results a viscous mass. Sodium chloride (or ordinary table salt) is added to this the mass is then thoroughly rinsed with alcohol and is finally submitted to the action of a press whose platform bristles with a number of fine metallic points or projections. These penetrate the mass forming tubes like those in an ordinary marine sponge known as *canaliculæ*"

The block thus obtained is of a spongy consistency and is both insoluble and unalterable in water It is smooth and pleasant to the touch and is not susceptible of putrefaction It is a very ingenious employment of the cellulose to which we owe so much

Removing Iodine Stains

TO remove iodine stains from bacteriological instruments or the hands a strong solution of hyposulphite of soda is good and effective The solution should be quite strong, and after its application the solution should be rinsed off with warm water and the stained article dried well.

New Evidence of the Origin of Man

The Earliest Known Inhabitant of Great Britain

Of all the chapters of science perhaps none is so romantic as that which contains the fragmentary narrative of the dawn of human life upon our earth. The story is written with skull and cross-bone hieroglyphics, and no suspense that ever novelist contrived in his reader can equal that which the student of anthropology feels in the intervals between the successive instalments" of the serial unearthed, here a page and there a page, now in the silt of a river in France, now on the banks of a German stream, or again, it may be, on British soil

When, in the thirties of last century, Boucher de Perthes first claimed to have found flint implements shaped in glacial times by human hands, he was greeted with ridicule. Since then we have become quite accustomed to placing the origin of man at least as far back in time as the glacial epoch. But our knowledge of the early history of our race is based on all too scant data, and every new discovery of a jaw, a skull, or a more or less complete human skeleton, is received with intense interest. The latest addition to our knowledge of primitive man comes from Piltdown Common, Sussex England. Here, in the gravels once forming the bed of the River Ouse, but now many feet above its present level, an English paleontologist, Mr Dawson, discovered, about a year ago, a fairly complete human skull representing the most ancient relic of the human race in the British Isles, and one of the oldest found anywhere. The results of his studies of the specimen have recently been made public Properly to appreciate the fine points of this find it is necessary briefly to recall some of the characteristic features presented to us on the one hand in the highest type of human skull, as represented in modern civilized man, and on the other by the various inferior types known to us in primitive man living or extinct, and in our humbler relatives, the apes.

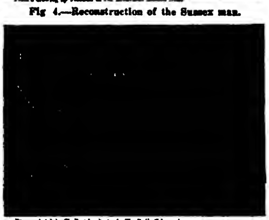
Considering first of all the jaw we have several interesting points brought out in our illustrations, Figs. 2 and 5. The former shows side by side the jaws of a chimpanzee, a Torres Straits Islander, and a European. Note how in the European the chin is seen projecting beyond the teeth, as seen from above. The chimpanzee and the Torres Straits Islander have no visible chin. This absence of chin, imparting to the face a snout-like appearance is typical of apes and low races of men, and is clearly indicated in our illustration of the newly found skull (Fig 6), though unfortunately the part of the jaw carrying the incisor and canine teeth is broken off and missing Another interesting feature should be noted In the chimpanzee the bone at the front of the jaw is quite wide, leaving a comparatively small open space in the angle of the jaw In the Australian native this space is larger, and in the European still more developed. When we remember the importance of the tongue in speech, this point acquires a marked significance

In profile view, as seen in Fig 5, several points of interest also appear The jaw of the ape and lower types of man is much more massive, and the notch in the upper end of the jaw—the sigmoid notch as it is called—is quite shallow in the ape, only slightly deeper in primitive, but is strongly developed in modern man.

As regards the brain case, the feature to which we naturally turn our attention first is capacity or cubical content. In this respect the newly discovered skull does not seem to stand as low in the scale as some specimens previously discovered elsewhere. A graphic comparison of the Sussex skull and the modern type is shown in Fig. 6. In this connection it is interesting to quote from Darwin

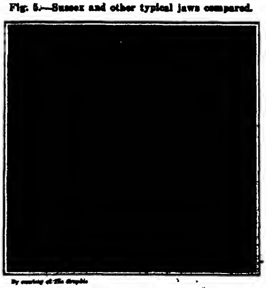
From a drawing by Forestier in The Illustrated London News

Fig 4.—Reconstruction of the Sussex man.



From a sketch by Sir Ray Lankester in The Daily Telegraph

Fig. 5.—Sussex and other typical jaws compared.



By courtesy of The Graphic

Fig. 6.—Skull of Sussex man compared with a highly developed modern type.

"Dr J Bernard Davis has proved, by many careful measurements, that the mean internal capacity of the skull in Europeans is 92.3 inches, in (native) Americans, 87 5, in Asiatics, 87 1, and in Australians, 81.9 inches. Prof Broca found that the nineteenth century skulls from graves in Paris were larger than those from the vaults of the twelfth century in the proportion of 1484 to 1426."

Another feature which gives a characteristic measure of the stage of development reached is the facial angle. This has been given as 62 degrees in the Neanderthal man, 57.5 degrees and 67 degrees for two fossil specimens found at Spy, and 56 degrees in the highest apes. Modern man has a facial angle of 80 to 85 degrees. It is the low facial angle, the absence of chin, the prognathous jaw, and the prominent orbital ridges over the eyes which give a characteristic and brutal appearance to primitive man, as pictured for us by Mr Forestier (Fig 4)

The brain capacity of the Piltdown skull is estimated at 1,070 cubic centimeters (65.3 cubic inches) It is interesting to compare with this the size of brain of some of the largest and most highly developed apes, the brain of the gorilla reaches a capacity of some 34 cubic inches. In this respect, therefore, the Piltdown skull might be said to stand about half way between the gorilla and modern man—neglecting the fact that the gorilla is more massive in body than man. Nevertheless, the Piltdown skull represents a considerably higher type, it seems, than the Neanderthal race, which has a much more slanting forehead. It appears, therefore, that at least one very low type of man with a comparatively high forehead was in existence in western Europe long before the low browed Neanderthal man became widely spread in this region. Dr Smith Woodward, who has been associated with Mr Dawson in his study of the Sussex skull, accordingly inclines to the theory that the Neanderthal race was a degenerate offshoot of early man and probably became extinct, while surviving modern man may have arisen directly from the primitive source of which the Piltdown skull provides the first discovered evidence.

One is naturally curious to know the age of the Sussex skull. The geologist is very cautious in estimating the age of fossils in years, but to make a very broad guess, it may be estimated that the Piltdown man lived some two or three hundred thousand years ago. Since that time the River Ouse has worn down its bed through a distance of eighty feet. The gravel bed in which the skull was found appears to belong to what the geologist terms the Lower Pleistocene age. The gravel consists largely of flints, among which many show signs of having been fashioned by human hands into rude implements. With the flints were discovered fragments of teeth of a Pliocene elephant and of a mastodon. Other remains were identified as belonging to a hippopotamus, a beaver, a horse, and part of the antler of a red deer

Such are the facts of the case. For those who like to give free rein to their imagination, there is ample scope for exercise in picturing the eventful life of primitive man, battling with wild beasts long since extinct, and, no doubt, engaging also in fierce combats with fellows of his own kind, for the frequent signs of violent injuries found in various fossil specimens attest eloquently to the strenuous struggle for existence that prehistoric man had to wage.

The Atoll Cloud

THE low-lying coral islands of the Pacific would be difficult objects for the mariner to sight at a distance, but for a curious meteorological phenomenon connected with them, to which attention has recently been directed by William Churchill. In his monograph on "Easter Island," just published by the Carnegie Institution, he says (page 50) "Even in the region of the lowest atolls a sailor's eye can read in the sky at enormous distances the loom of the land. The lagoon of Anaa reflects the sunlight which shimmers on its unruffled surface and casts so distinct a green hue upon the trade-wind clouds which it creates that its existence may be known as far upon the sea as if it were piercing the heavens a mile high instead of lying on the waves scarcely as elevated as the seas which shatter in tumult on its reef."

The characteristic green cloud formed over an atoll Mr Churchill has named elsewhere[1] the "atoll cloud." In a letter on the subject he gives further particulars

"I have picked up this island (Anaa) perhaps a score of times, and the same holds true in varying degrees of other of the Tuamotu atolls. I recall the same observation of Jaluit in the Marshalls, of Liueniua (Ongtong Java) off the Solomon Islands, and possibly of yet another great atoll in the same neighborhood. My attention was first directed upon the phenomenon by Polynesian sailors, but as soon as the eye has once caught the appearance of the cloud in the sky it is thereafter as unmistakable as the loom of the land itself. I may describe it as a characteristic pale green tint upon a thin white (fleecy cumulus) cloud, the tint being nacreous, but not quite so pronounced as the shade of the California abalone shell

"Anaa is a very typical instance. The lagoon is a still sea with much of its depth under two fathoms. The strand facing the lagoon is so flat that a ripple of no more than half a vertical inch will wet as much as fifty feet of sand. Water temperatures in the shallows have been noted between 35 and 37 deg. Cent. (95 to 98½ deg. Fahr.) I can find no record of sand temperatures on the beach, but you will see that they must run high, and, of course, they will prove a potent factor in evaporation when you recall what an acreage is dampened by the higher ripples and immediately exposed to evaporation under the hot sun Physically we have no difficulty in seeing what happens. We have a large still surface of shallow water with a maximum of evaporating surface upon almost level beaches, a hot sun acting thereon, a flat land without elevations to interrupt the upward movement of convection It may enter into the problem that this evaporating surface is surrounded by an ocean of cooler water Evaporate this big pan, and you have an upward current of air carrying aqueous vapor up to the region where it becomes saturated, and, therefore, visible as a superimposed cloud. The still lagoon also serves as a mirror of many miles' area reflecting from its light green surface the rays of the sun."

The same process of rapid evaporation and convection over an island sometimes gives rise to a cloud below the general level of the trade cumuli and differing from the latter in direction and velocity of drift. This phenomenon is described in a letter from Lawrence Hargrave, the Australian inventor of the box-kite.

"Those who understand such things can often tell the position of an invisible reef or shoal by seeing a stationary cloud apparently ploughing its way through the ranks of the steadily moving trade clouds. If one be supposed to be above the clouds, this may be likened to a foam-flecked river passing a white stone projecting above the water. When there are no trade-wind clouds, a stationary cloud is still often an indication of reef, shoal, or island."

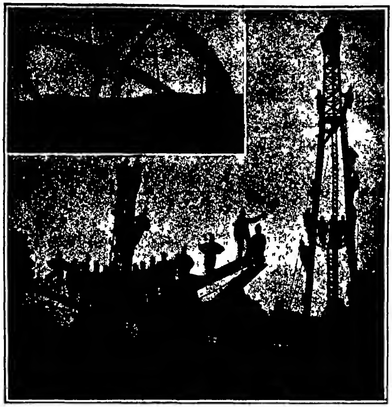
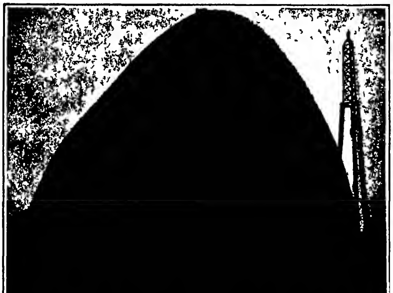
New Hangars for Military Uses

By Our Paris Correspondent

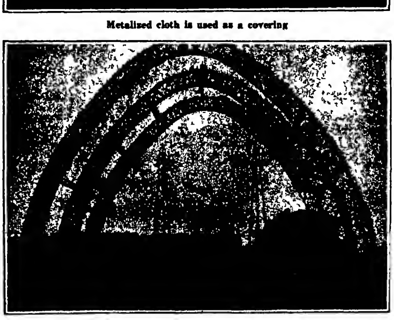
THE question of providing suitable hangars for air ships is receiving much attention in military circles in the leading countries of Europe, in order to keep pace with the development of airships for army use Such hangars may be divided into two general classes, one of these being a balloon shed of the fixed and permanent type which is erected once for all and belongs to certain military aeronautic establishments Up to the present it is the permanent hangar which has received the greater share of attention on the part of designers and constructors, but not less important is the type of movable shed which is also needed as part of the army material in order to give a suitable shelter for airships when carrying out military operations in various places where they may be at a considerable distance from any of the permanent posts. The question of a portable hangar is also the object of research on the part of constructors, and we illustrate one of the most recent ideas of the kind which has been brought out in Italy, this being the Bosco and Donadelli system, and it is worthy of note for several reasons. As several of our engravings show, it has been tried in field work by the aeronautic corps of the army



Arches in the course of erection. The pillars are built up of hinged sections.



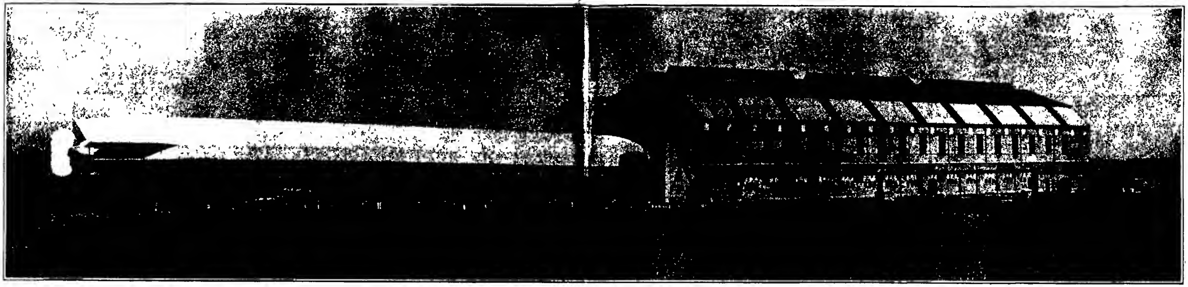
Metalized cloth is used as a covering



Each arch is built up in sections on the ground and is then raised into position.

The different sections which make up the arches are locked together by using a hinge clamp which is peculiar to the present system. Toothed projections on one piece fit into recesses on the opposite piece like the two halves of a hinge so that when placed together, all that is needed is to run a pin through the matched holes in order to couple the two pieces. Each arch is made up of a certain number of sections which are thus joined together, and there are two separate hinge joints used at the meeting point After locking one joint as we have seen, this forms a hinge so as to bring the other joint into place and it is then ready to be locked as before by means of a pin so that the two sections are tightly fixed together by means of the two joints. To dismount the sections, the only operation needed is to withdraw the two locking pins so that the joints readily come apart In this way the arch is built up while it is lying on the ground, and is then ready to be mounted in an upright position. At the proper points on the ground the base plates are laid which form the foot of the arch Each plate carries projecting lugs in the shape of a half hinge These are made to match with a like part on the arch end so as to make the joint After running a pin through the hinge while the arch is lying on the ground, the last is raised to the upright position by using ropes and pulleys, and when in place, the second joint between base-plate and arch now matches and this is fixed by driving in a pin, so that the arch is now fixed to the base-plate very strongly The second arch is now raised in the same way and the two are bound together by cross brace pieces of structural iron work as will be noticed, and so on until the right number of arches is erected

Another point in the assembling of the hangar needs to be considered, this being the erecting of the structural iron poles or towers which are required in order to draw up the arches by means of cables. It has been a problem to set up such towers in the proper way in field work, as they must have a considerable height in order to serve for handling the arches and at the same time must be very strong in view of the great weight of the arch The Italian constructors make use of the hinge joint principle in a very good way for mounting the towers. In the first place a short structural iron pole is fixed on the ground upon the base plate so as to form the lower and center part of the tower It carries a set of pulleys at the top for use in raising the rest of the tower in place The base plate is triangular, and at each end of the triangle a beam of the tower is fixed by means of a hinge joint This beam is in reality double, having a hinge placed at the middle upon its height, but both sections of the beam can lie on the ground owing to the hinges. All three beams come together at the outer or top ends and are hinged to a single top pole or cap. The whole can be assembled with the sections lying on the ground with the exception of the top cap, which fits down over the middle post When the hinge joints are



The "Zeppelin II" coming out of the great hangar at Cologne—one of the largest of its kind in existence.

assembled the whole is drawn to an upright position by ropes and pulleys and in this position the second joints between the various pieces all come together so as to be locked in place by pins thus making a three-sided tower with its capping and the whole construction is very solid.

In dismantling the tower the men climb to the top and draw out one of the hinge pins at each locking point leaving one joint which acts as a hinge as before. The tower is then lowered as a whole in the same way as it was raised. All these operations can be carried out in a short time. When the first two arches have been raised and bound together the tower is no longer essential for the arch structure can now take its place so as to carry the ropes for raising the other arches of the hangar.

A new fabric is used for the covering material comprising a metallized cloth which has great strength and is also weather proof. It hangs down at each end of the hangar as a double curtain which can be drawn apart at the sides. The dimensions of the new military hangar of the present standard type are 270 feet length by 100 width and 80 height. A very good speed in mounting is assured and all can be put together within two days. When transportation by railroad is necessary the metallic pieces with the covering and all needed parts are carried on a train of 21 cars.

An example of recent construction as regards the other class of hangars, that is the permanent balloon sheds, is shown in the type which has been erected at Cologne by the Augsburg-Nurnberg machine firm in order to house the Zeppelin airships. This hangar is noteworthy as being one of the largest of the military balloon sheds yet to be erected. One of the points which occupied the designer's attention was the operating of the huge double doors at the end of the hangar. In spite of the great size of these doors a suitable method of electric motor drive enables them to be opened in 4 or 5 minutes. The total length of the present hangar is very nearly 500 feet, its width 170, its height 92. The double doors are 82 feet high and each door is 34 feet wide.

Cost Estimates of Horse and Motor Trucks

By John Ritchie Jr

As noted in the SCIENTIFIC AMERICAN of June 22nd last a careful study of comparative costs of vehicles is being made at the Massachusetts Institute of Technology, under the supervision of Dr. Harold Pender and the direct management of research associate H. F. Thomson. The researches of the Institute during the past summer and fall have been in the nature of an inquiry into tire costs, repair costs and other expense matters and are reported in Vehicle Research Bulletin No. 2. Some notion of the amount of work involved in the research may be gained from the statement of Mr. Thomson that more than one hundred thousand observations have been taken upon the performance of wagons engaged in their daily work upon the streets and roads not only in Boston but in New York, Chicago, Philadelphia, Washington, St. Louis, and Detroit as well as in a number of smaller places within the same extent of country. There have been thousands of tapes from registering devices and other thousands of corroborative observations attesting the facilities of the Institute for collecting and digesting such scientific material.

Relations Between Annual Cost of Motor Trucks And Characteristics of Service

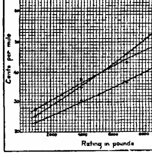
	Tires	Repairs	Battery Renewals	Lubricants	Electricity — Gasoline	Garage Expense	Painting	Driver and his pay	Amortization or Depreciation	Interest	Insurance	Administration and Taxes
(a) Character of work												
Size and type of truck	x	x	x	x	x	x	x	x	x	x	x	x
Nature of loads	x	x	x		x		x	x	x		x	
Number of stops	x	x	x	x	x	x	x		x			x
Distance per day	x	x	x	x	x				x			
Number of hours per day	x	x	x	x	x				x			
Days in service	x	x	x	x	x	x		x				
(b) Roads and climate												
Road surface	x	x	x		x				x			
Grades		x	x		x				x			
Other street traffic		x	x		x						x	
Climate	x		x	x	x		x					
(c) System of operating												
Routing		Indirectly as this item affects distance										
Loading and unloading		Indirectly as this item affects distance										
Overloading	x	x	x	x	x			x	x			
Overspeeding	x	x	x	x	x			x	x			
Garage facilities		x	x		x	x	x		x		x	x
Care of cars	x	x	x	x	x			x	x			x

Table showing by x's what service conditions affect the various expense items.

It is practically impossible to predetermine what will be the total annual cost of operating a truck at given rating, without knowing what will be the requirements of the service, the nature of the road and the general method of handling and repairing for the cars. To illustrate the difficulties involved in making up such an estimate the accompanying table has been prepared showing the relations between the various items of expense and the character of the work to be done, the nature of the roads and climate, and the system of operation.

In the expense for tire renewals the bulletin places the average mileage cost for the five ton electric at about 8 cents and for a five-ton gasoline about 9 cents, the corresponding data for the three ton car being 3½ cents and 4 cents. Several of the light gasoline cars which have been reported have been equipped with pneumatic tires, in which cases the mileage cost was as much as twice that for the solid tire equipment on the machines of the same size. Referring to the reports upon the apparent repair expense it is found that for the electric truck this expense is practically as great for the large cars as for the small ones. In the small sizes the reports in special cases show a cost considerably in excess of that commonly referred to by car manufacturers. With the gasoline machine the repair expense in the majority of cases where the car has undergone a thorough overhauling is far in excess of the manufacturer's figures, the average being from one and a half to two times as great. The reports for garage expenses are very irregular ranging all the way from $11 a year to $450 and averaging about $200 per year. The average consumption of electricity for electric trucks with lead batteries, ranges from about 500 watt hours per mile for the light delivery wagon to about 1,200 watt hours for the five-ton truck. The number of miles per gallon of gasoline varies from three to four miles for the four, five and seven ton machines to about nine miles for the light cars.

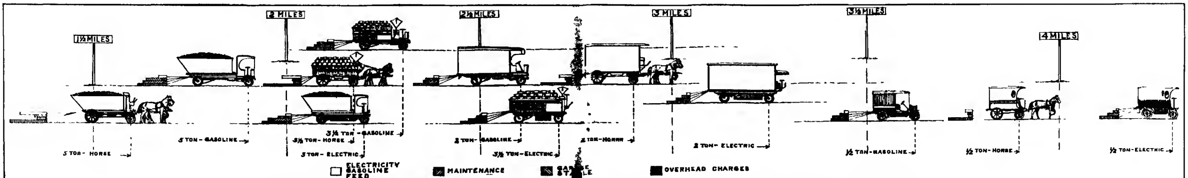
Four estimates have been made whose details are based upon the performance study (the full results of which study are not yet ready for publication) and upon the cost information presented in Vehicle Research Bulletin No. 2. The total comparative expenses per delivery as given in these estimates are plotted against the size of the truck in the accompanying chart. The respective curves for the horse, gasoline and electric wagon indicate that the power wagons have an increasing superiority over the horse wagon with an increase in size. The vehicles chosen for the estimate are of one thousand, four thousand, seven thousand and ten thousand pounds rated capacity respectively employed in parcel, furniture, draft beer and coal delivery. The territory covered in each case is assumed to be within four miles of the loading point. The expense items have been grouped under the head of (1) electricity, gasoline or feed, (2) maintenance including tires or shoeing, repairs, battery, veterinary, lubricants, (3) garage or stable, driver and helper, (4) overhead charges including depreciation, interest and insurance. The accompanying drawing is based on these estimates and shows the comparative distances that can be covered by the various types of vehicles at an expenditure of $1. Each vehicle is dragging behind it its load of expenses per mile, the separate bars of the load representing fuel, maintenance, garage or overhead charges as indicated by the legend. The cars have all started from a common starting point and before the half ton electric vehicle has run up one dollar's worth of expenses it has covered a distance of four and one third miles while for the same outlay of money the five ton horse drawn coal truck has covered but a mile and two thirds. The other vehicles are distributed between these limits as shown in the drawing. In these estimates the expense for electricity has been placed at 5 cents per kilowatt hour, that of gasoline at 15 cents per gallon and of feed at $100 per head per year. As shown in the chart the total expense per mile for the half ton electric vehicle is 23 cents. How this amount is divided up into the various items of expense is indicated by the length of the bars constituting the load that drags behind the vehicle. The same is true of all the other vehicles. The expense loads are all drawn to the same scale so that it is a simple matter to compare any vehicle with any other by measuring the relative lengths of the bars.



Estimates of total expense of 1 ton parcel, 2-ton furniture, 3½-ton keg-beer and 5-ton coal trucks.

Testing Eggs by Roentgen Rays

A LARGE association of English poultrymen which delivers 200,000 eggs per week to London merchants has for some time made successful commercial use, according to *La Technique Moderne*, of the Roentgen ray apparatus for testing the freshness of eggs. The lamp is inclosed in a box impervious to light except on one side in whose wall an opening proper for the reception of the egg is made. An absolutely fresh egg when placed therein appears perfectly transparent. Eggs which are older, even if still edible, show small spots. These are not visible to the naked eye in ordinary light but are shown on the fluorescent screen of the apparatus quite clearly. When such spots exceed a certain size the egg is declared unfit for food. These examined eggs, which are certified by a stamp, are already much sought after in the London market.



The trucks have run as far as they can on one dollar. The distances they have covered may be judged from the mile-posts. Dragging behind the vehicles are bars indicating the expenses charged per mile against each truck.

A dollar race, based on estimates compiled by the Massachusetts Institute of Technology for short distance truck service.

What Motor Truck Would Suit Me Best?

A Composite List of American Motor Trucks and Delivery Wagons Arranged According to Carrying Capacity

Compiled by Theodore M. R. von Kéler

To arrange commercial motor vehicles according to price is almost impossible, as the great majority of both heavy and light cars are furnished with bodies suited to the special needs of the purchaser. This list, therefore, has been based upon the carrying capacity, and the prices in most instances apply to the chassis, fitted with driver's seat. Bodies in a great variety of forms are furnished by the manufacturers at prices ranging from $100 upward.

The majority of truck manufacturers are willing to sell to small merchants on easy payments, and to supervise the installation of motor service by means of their own service departments.

As in the list of pleasure cars published last week, the many small companies of purely local importance have been omitted, and only the leading models have been listed. Besides the factories named herein there are nearly one hundred companies which have been formed within the last six months, and whose prospective output will not fall short of 5,000 trucks during the coming year. As yet their product has not reached a stage which would warrant its listing in a national periodical.

Capacity 500 to 1,000 Pounds.

Anderson Elec Car Co., Detroit Mich ($2,845)
Bessemer Motor Truck Co, Grove City, Pa. ($1,250)
Bowling Green Motor Car Co. Bowling Green, O ($1 200)
Chase Motor Truck Co Syracuse, N Y ($500)
Commerce Motor Car Co., Detroit, Mich ($750)
Dart Mfg Co, Waterloo, Iowa. ($750)
Durant Dort Carriage Co., Flint, Mich. ($750)
General Vehicle Co. Long Island City, N. Y ($1 370)
Hupp Motor Car Co., Detroit, Mich ($950)
Ideal Auto Co. Fort Wayne Ind ($1 500)
McIntyre W H Co., Auburn Ind. ($600)
Mercury Mfg Co., Chicago, Ill. ($750–$900)
Moon J W Buggy Co. St. Louis, Mo ($1 150)
Studebaker Corp., South Bend, Ind ($1 500)
Sullivan Motor Car Co. Rochester, N Y ($925)
U S. Motor Co. Detroit, Mich ($1 400)
Ward Motor Vehicle Co., New York city ($1,200)
Waverly Co., Indianapolis, Ind ($1,800)

Capacity from 1,001 to 2,000 Pounds.

Adams Bros. Co. Findlay Ohio ($2,100)
Alden-Sampson Mfg. Co. Detroit, Mich ($2 000)
Anderson Elec Car Co, Detroit Mich ($2,870)
Atterbury Motor Car Co, Buffalo, N Y ($1 500)
Available Truck Co. Chicago, Ill. ($900–$1 350)
Avery Co Peoria, Ill ($2 000)
Bessemer Motor Truck Co. Grove City, Pa. ($1 800)
Bowling Green Motor Car Co., Bowling Green O ($1 600)
Brown Commercial Car Co Peru, Ind. ($1 650)
Buick Motor Co. Flint Mich ($1 000–$1 400)
Chase Motor Truck Co. Syracuse N Y ($1 250)
Chicago Pneumatic Tool Co, Chicago, Ill ($1 050)
Croce Auto Co Asbury Park, N J ($1 850)
Dart Mfg Co Waterloo Iowa ($1 100)
Durant Dort Carriage Co. Flint Mich ($1 375)
General Vehicle Co Long Island City N Y ($1,710)
Gramm Motor Truck Co, Lima, O ($1 750)
Harwood Barley Mfg Co. Marion Ind.
Hexter Motor Truck Co., Lima, O ($1 750)
Hupp Motor Car Co., Detroit, Mich ($750)
Ideal Auto Co Fort Wayne, Ind ($1 750–$2,000)
International Motor Co., New York city ($2 500)
Kelly Springfield Motor Truck Co., Springfield O ($2,000)
Kissell Motor Car Co., Hartford, Wis. ($1 500)
Knickerbocker Motor Truck Mfg. Co., New York city ($2,000)
Koehler H J Co New York city ($750)
Krebs Commercial Car Co., Clyde, O ($1,375)
Lauth Juergens Motor Car Co., Fremont, Ohio. ($2 100)
Lippard Stewart Motor Car Co., Buffalo, N Y ($1 050–$1 675)
McIntyre W H Co Auburn, Ind ($1 500)
National Motor Truck Co Bay City Mich ($1 225)
Nyberg Automobile Works, Anderson Ind ($1 300)
Oakland Motor Car Co Detroit Mich ($1 500)
Piggins Motor Truck Co Racine Wis. ($1 750)
Pope Mfg Co Hartford Conn ($1,750)
Poyer D F Co Menominee, Ind. ($1 200–$1 500)
Reo Motor Truck Co Lansing Mich ($750)
Rowe Motor Mfg Co Coatesville Pa ($1 700–$2 100)
Sandusky Motor Truck Co Sandusky, Ohio. ($1 400)
Sanford Motor Truck Co Syracuse N Y ($1 080)
Selden Truck Sales Co Rochester N Y ($2 000)
Service Motor Car Co. Wabash Ind ($1 350–$1 475)
Stewart Motor Corp. Buffalo, N Y ($1 650)
Studebaker Corp., South Bend, Ind ($2,000)
Sullivan Motor Car Co Rochester, N Y ($1,050)
Transit Motor Truck Co., Louisville, Ky ($1,850)
Universal Motor Truck Co., Milwaukee, Wis. ($1,950)
Velie Motor Vehicle Co., Moline, Ill. ($2 000)
Ward Motor Vehicle Co., New York city ($2 000)
Waverly Co Indianapolis, Ind. ($2,150)
White Co., Cleveland O ($2,100)
Wilcox Motor Car Co., Minneapolis, Minn $2,300)

Capacity from 2,001 to 3,000 Pounds.

Adams Bros. Co. Findlay Ohio ($2,300)
Alden Sampson Mfg. Co., Detroit, Mich ($2,500)
Anderson Electric Car Co., Detroit. Mich. ($3,132.50)
Atterbury Motor Car Co., Buffalo, N Y ($2 400)

Notes and Queries.

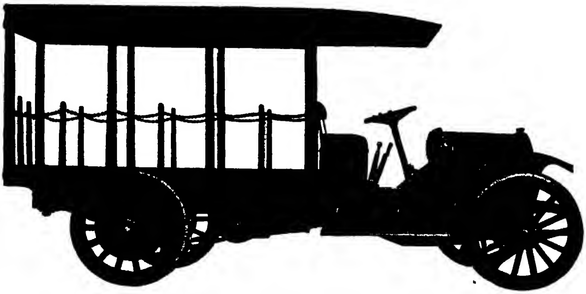
Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12726) F W M asks An upright, tight, heating drum, 5 feet high, 8 inches diameter having 3¼-inch top connection (no damper) to chimney and inside, on bottom of drum a ring burner of 1-inch pipe for gas, with Bunsen air mixer taking air from outside, and also a 2-inch bottom connection to take in fresh air into drum. The gas will not burn in the ring burner inside of drum It blows out. Why? A If your Bunsen burner has a greenish color at the bottom of the flame and vibrates and snaps out, there is not sufficient air furnished by the mixer There should be an adjustment to control the amount of air admitted to the gas, so that the burner will burn quietly and with a flame almost colorless when seen in a lighted room.

(12727) J W asks I would very much like to know if there is any truth in a certain French chemist, who states that he has made the diamond in the rough Some time ago I read in an editorial (have forgotten whether it was in your paper or some other paper) of its being done, and told it to a friend who claims it cannot be done I would be very much obliged if you would let me know about it A. You are not misinformed that diamonds have been made artificially The process is described in SUPPLEMENTS 1551 1552 1553 price ten cents each, in a lecture by no less an authority than Prof William Crookes. These stones are very small, however the largest being about three thousandths of an inch across They are conceded to be real diamonds, and if small ones can now be made, perhaps some time large ones may be made. The 'certain French chemist is none other than the famous Moissan the man who has almost created the use of the electric furnace. We should say there is truth in any claim he may make.

(12728) P M asks 1 Why the sun appears to set at an earlier hour say about December 16th than it sets December 21st or 22nd the winter solstice A The sun sets just as long *after* noon as it rises *before* noon all the time, every day in the year The clock however does not stand at 12 at noon on any day of the year, with the exception of four days, about April 15th, June 14th September 1st and December 24th but the dates vary a little from year to year partly because of the extra day inserted in leap years. The subject is too extensive for discussion in a letter and is explained in all the text-books of astronomy under the caption Equation of Time You can doubtless in your city library find Todd's "New Astronomy or Young's Manual of Astronomy either of which will cover the subject. 2 Why is it that at certain seasons the sun rises later every day but, at the same time sets at the same hour and minute, over a period of say 8 or 10 days? A. Your second question is answered by saying that sunrise and sunset are calculated and given in the almanacs for the real sun but the clocks do not keep the time of the real sun since the apparent motion of the real sun is not uniform day by day Hence the apparent difficulty which is explained in Todd on page 113 under the heading Retardation of Sunset near the Winter Solstice.' Should you wish to own either or both of these valuable books, we can furnish Todd's "New Astronomy' for $1 45 and Young's Manual for $2.50 and shall be pleased to receive your order We thank you for your expression of appreciation of our astronomical articles.

(12729) F M asks How are trees splintered by lightning? Not long ago I examined the result of lightning on a large tree. Some large limbs that lay on the ground showed that each small twig and limb had a hole bored its length just under the bark. I could not find any entrance or exit holes, but cutting showed this one hole in the section, and charring was not in evidence. I took several of the sticks home, but cannot find them now When the current gathered at the trunk it was too much for the carrying capacity and splintered the wood in seeking an onward path and the limbs fell. Was not the tree's conductivity the sole cause for the effects? Had the tree been dead and dry, it would have been splintered much worse. Lightning follows the fiber whether the tree is dead or alive, straight in the limbs and more or less spirally in the trunks. The great Maxwell believed heat, light, and electricity to be the same i. e vibratory Why could not the vibrations of electricity crowd themselves on a poor conductor sufficient to tear it apart? A We thank you for your observations upon the action of an electric discharge upon the wood of a tree. All non-conductors are ruptured by the dissipation of a heavy charge of electricity upon or through them. The trees and wood generally form no exception to this general effect. Conductors are not thus affected, since they allow the dissipation to take place without resistance on their part The better a non-conductor, that is, the poorer a conductor a material is, the more is it rent into pieces by an electric shock. Light, heat, and electricity are regarded by scientists as manifestations of one energy, differing principally in wave length. All these are electro-magnetic effects. Lightning only differs by the magnitude of its display.



The 3/4 Ton Utility Truck—$1250

(*Chassis Only*)

THIS new Utility truck is the most practical and serviceable truck of its size ever built. It is intended for any kind of city and suburban delivery service. It works more simply, more economically, more rapidly and more effectively than most trucks of much larger size. It is a new development.

Unlike the average small truck, it is *not* a built-over or a redesigned pleasure chassis. It is a real heavy truck in all of its parts, in its entire design, in its whole construction and in its economical operation. For instance, the powerful 4-cylinder motor is controlled by our patented governor; it cannot be driven over 18 miles an hour; it has quick demountable solid tires 36" x 3" front and 36" x 3½" rear; it has an unusually rugged pressed steel frame, doubly reinforced at points where it will receive the greatest strains; the wheel-base is 120 inches.

Throughout this truck is built on the most modern truck lines. It is made in one of the largest truck plants in the world by men who have been building successful trucks for over ten years It is built by truck specialists.

For the merchant or manufacturer who has a whole lot of daily deliveries to be taken care of, this new Utility truck is well worth immediate investigation.

See the nearest Gramm dealer, or write us and we will send you one of our transportation experts.

Literature and transportation advice from the factory—gratis.

See this new truck at the Chicago Truck Show

Section D, Coliseum

The Gramm Motor Truck Company, Lima, Ohio

John N. Willys, President

BRIEF SPECIFICATIONS

CARRYING CAPACITY—1500 lbs. Maximum, 2000 lbs.

BODY—Optional and extra.

FRONT AXLE—[illegible] Section. Timken bearings.

REAR AXLE—[illegible] Section, [illegible] bearings [illegible].

MOTOR—4 cylinders, 4 in. bore—4½ in. stroke. Provided with enclosed and sealed governor

TRANSMISSION—Selective type. Three speeds forward and one reverse.

WIDTH OF FRAME—34 inches

WHEEL BASE—120 inches.

TIRES—Front, 36x3, Rear, 36x3½ Goodyear Solid

LOADING SPACE — Approximately, 48 inches x 96 inches.

GASOLINE CAPACITY — 20 Gallons.

EQUIPMENT — Two side oil lamps Oil tail lamp, horn, and full set of tools.

The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons The Editor will endeavor to answer any questions relating to mechanical features operation and management of commercial motor vehicles

Business Getters for Small Concerns

By Charles H Spencer

BEFORE the experiment was made the small user considered the motor truck out of his reach When the motor truck salesman called the usual response was, Let the big fellow do it. We can t. They have to do things on a big scale. Their plants are large They can afford to get fleets of cars to hire skilled and expensive men to take care of them to buy gasoline at reduced rates and to profit all along the line by purchasing in volumes reaping the benefit of cost reduction by so doing There seems to be plausibility and business discretion in this argument until analysed Then it will be found that like nearly every proposition which is opposed to progress it is based on unsound reasoning, The business man who resigns himself to a small volume of business and is not concerned in installing facilities for handling an increase is never likely to get the increase

Customers Beyond the Horse s Reach

The city merchant not equipped with the commercial vehicle is now finding himself compelled either to abandon the efforts to secure the business in the suburban trade or to expend a sum of money on horses and suitable wagons that consume his profit and make his venture unprofitable The man using horses has to limit himself to the area in which the animal has to deliver Farther than this the country is closed to him There may be thousands of customers beyond the boundary line of the horse s power It is generally agreed that a ten mile radius is about the limit in which it is possible to use a horse-drawn delivery system By the time a horse has hauled a load for ten miles made many stops and completed the ten mile journey back it has done about all the work possible for him When any more than twenty miles daily is piled on the animal it is done at a risk it means perhaps the collapse of the horse a dead loss to the owner and permanent impairment of his delivery system

The electric vehicle ideally adapted to quick delivery within the city limits or to suburban points is good for a radius of from twenty to twenty five miles a day going and coming and finally a gasoline propelled motor truck is in many instances delivering at distances of fifty miles from its starting point which means that it covers a delivery route of one hundred miles a day

A Wholesale Grocer's Experience

A short time ago the writer s attention was called to a wholesale grocer who decided he did not have enough customers to support the overhead expenses of his store He decided to create a small field of action and for this reason he picked out a truck He was prepared to have it cost him a little more money just as he believed in spending additional money for advertising or increasing the salary of a productive salesman The results he obtained were very prompt in forthcoming His truck went where his wagon never before could reach and he found that there was business waiting in sections he little dreamed of. He put on more salesmen who in this way were given the advantage of being able to promise prompter deliveries than they had been able to maintain before The increase was so rapid, and the profit so big that this particular grocer was obliged to put a new truck into service to care for the gain.

We know of a similar instance with a small retail ice concern that was competing with a large concern using horse-drawn vehicles. In less than a year's time after introducing a commercial truck, he was obliged to purchase an extra car and is now making wonderful increases in his business, and inroads into the trade of his competitor through his ability to serve his patrons more promptly

Another instance is of a retail grocer who found that a 1½ ton commercial vehicle displaced four horses and two wagons. This concern averages sixty miles per day now by the use of the motor truck and has extended the business territory of the company to a surprising degree New customers have been made and held by the promptness of delivery assured and the residences situated in unfrequented sections are reached where these were formerly a problem of great difficulty being visited weekly where now the motor truck calls daily

Making Chauffeurs Out of Drivers.

Many business men are deterred from buying motor trucks for fear their wagon drivers cannot learn to be chauffeurs There is no more intelligence required to operate and take care of a car than to take proper care of a horse There are a few motor truck manufacturers who conduct special schools for drivers at their different service buildings located in the various large cities of the country and it is their experience that the average teamster can be readily educated to operate a car One concern turned out last year over fourteen hundred students in one of these schools who were formerly drivers and reliable delivery men used in the days of the horse-drawn vehicle

The Right Car for the Purpose.

It has been found in many instances that a merchant has paid too little for his motor truck or has purchased a car too light in construction to withstand the daily delivery grind or too large for the particular handling of his merchandise There are over two hundred and sixty firms engaged in the manufacture of motor trucks in this country and it requires little effort to secure practically all the needed information regarding the particular type of truck that is meeting with success in the line of business in which the merchant is interested On looking carefully into the subject it is usually to be found that the best car for a particular line of business is the type that is already represented in greatest numbers in that line

Steel Tires in France

To the Editor of the Motor Truck Department

In the article on Subsidized Motor Trucks appearing in your issue of Sept 28th 1912 a statement was made which was very misleading for the reason that it was incomplete It referred to the French government test, and the assertion was made that "not one of the trucks shod all around with steel was able to qualify The author evidently did not know that this applied only to trucks of three tons capacity and less, in other words light trucks intended to be driven at speeds of about twenty miles per hour Thomas S Fay former president of the American Society of Automobile Engineers, who carefully investigated the French army test of steel tire trucks, said "Not a few makers of automobiles maintained that pneumatic tires would be even cheaper and better in the long run than solid rubber tires, thus suggesting strongly that steel tires were out of the question. But the French army had its way and their decision has had a marked influence on commercial transportation in France. To-day practically all French trucks over three tons capacity are fitted with [illegible]

of steel tires for the motors used by the armies of Germany, Austria, Russia and Japan, and steel-tired trucks are now being introduced into this country. To adapt a motor truck for steel tires, particular attention must be paid to the spring suspension of the chassis. The springs must be unusually long and flat so that they will have a maximum of resiliency. They must also be hung in such a way as to permit of side sway. The wheels must have very thick felloes, and hubs of wood with many substantial spokes. Motor trucks thus constructed may safely be driven at speeds up to ten miles or even fifteen miles per hour.

J. Jaccard & Co.

Abuse of Good Roads

By Arthur C. Brady

MUCH is written and a great deal of gossip is current regarding the abuse inflicted on good roads by the automobile.

The writer has made several personal examinations of new roads that have been opened and finds that the trouble charged to the automobile in this respect is very much exaggerated. The evidence seems to point to the fact that it is a combination of horse and automobile which interferes with road conditions.

In a recent walk of five miles over a new State road, opened only about a year ago between Millbrook and Poughkeepsie, the evidence was conclusive throughout the entire distance that it was the sharp calks of the horse-shoes that started the deterioration. This road had been covered with some oil substance which had made a very compact smooth surface and which was capable of shedding water. This surface was not broken or damaged in any way by the automobile service traveling over it, although a speed of 50 miles an hour is not unusual on this road. The print of every horse-shoe was distinct, however, and the calk cut through this cover, making an opening where the water finds its way through, thus giving a hold for the automobile tire to pick up small particles of dust and start an opening which soon grew to a size requiring attention.

It is always easier to point out the difficulty than find the remedy. Unless horses can be driven over State roads with rubber shoes, they are a great detriment to the wearing qualities, and in view of the fact that we are spending millions of dollars every year for good roads, I think it is worth consideration to look the matter straight in the face, and either arrange to build roads that will stand both horse and automobile wear, or equip horses used for road work with shoes that will not penetrate to a depth of ¼ inch as the calks do where newly shod horses are traveling at a fast gait.

Motor Truck Queries and Answers

J. P. B. asks: Will the next few years bring many changes in the design and construction of commercial motor vehicles?

A. This is a question frequently asked by prospective users, and their failure to secure a convincing answer is probably delaying many from purchasing motor vehicles. Practically every motor truck engineer will assert that the changes will be limited principally to minor refinements and improvements, which will make the vehicles of to-morrow but little better than those of to-day. Irrespective, however, of what the future may hold in store, the motor truck of to-day is a highly developed and very practical transportation unit, and no unjustified fears of radical changes in the future should influence those debating its adoption.

A. L. P. asks: Is there any advantage in the motor truck with the motor in front under a hood, as in pleasure cars, over the truck with the motor under the seat?

A. With the motor under the driver's seat it is possible to have a shorter wheel base and over-all length. Where a very long body is used or where many turns have to be made in narrow streets this is naturally an advantage. On the other hand, there are a number of advantages

claimed for the motor in front under a bonnet This construction brings more of the load weight on the rear axle, where it properly belongs and can be readily cared for enabling the use of lighter spring suspension in front, where the power and driving mechanism is located, both of which need to be relieved of jar as much as possible. It provides easier handling of the vehicle and a more accessible power plant. In its new specifications pertaining to motor trucks eligible for subsidy the British War Department bars all vehicles not having motors in front.

IN the SCIENTIFIC AMERICAN of October 26th 1912 was an article by Mr Morris A Hall on the delivery service of New York's department stores in which it was stated that the saving of the trucks over horses was found by Stern Brothers to be $1 012 a year for each motor driven unit The figure should have been $2 112

Moving and Talking Pictures

(Concluded from page 65)

the film after exposure The Court of Appeals for the Second Circuit (see 151 F R 107) held claims 1 2 and 3 valid, but not infringed by a camera in which the film is moved by frictional contact alone although such construction is within their terms if construed without reference to the words substantially as described But they held these claims were infringed by a camera in which the film is moved by a reciprocating two-tined fork carrying studs or pins which engage perforations along the edges of the film This construction was considered the substantial equivalent of the sprocket wheel of the patent Claim 4 was held void as too broad. It differed from claim 3 of the original by the additional words the periods of rest being greater than the periods of motion

The reissued patent was again reissued as No 13 329 with five claims Claims 1 2 and 3 thereof are the same as the corresponding claims of the previous reissue Claim 4 differs from claim 1 in stating that the feeding devices comprise means proportioned to cause the devices to so advance the film that its periods of rest shall exceed its periods of motion Claim 5 differs from claim 1 in stating that the film is perforated and specifying that the feeding devices are provided with teeth engaging the perforations of the intermediate section

In a suit brought by the Motion Pictures Patent Company (owners of the Edison patent) against the Chicago Film Exchange the validity of the reissued Edison patent was again passed upon The lower court held the claim covering the photographic film infringed but on appeal the decision of the lower court was reversed the court taking the position that the long pliant translucent celluloid film with the sensitized surface was the invention and improvement of others. The pictures taken on such a film are photographs The invention of Edison was exhausted with the construction of a camera which enabled the photographs of moving objects to be taken on the Eastman film in the distinct, uniform and satisfactory manner justly claimed for them The pictures taken are the direct result of the mechanism of the camera with the Eastman film mechanically adapted to and applied thereto' The perforations along the edges of the film at regular intervals, into which perforations the teeth of ratchet wheels entered to give it the required motion was regarded as a mere mechanical contrivance devoid of patentable novelty

A large number of patents have been granted for various improvements in motion picture machines, and to describe them all would fill a large volume. An interesting apparatus was patented by R. D Gray, No. 540,545, June 4th, 1895. Referring to Fig 4 the film *D* is shown passing from the reel *F* to the reel *L*. The film receives two series of exposures, the individual exposures being made [illegible]nately on opposite sides of the median line of the film and through a single lens

B A segmental mirror *E* shown in elevation in Fig. 3 consists of a half circle of silvered glass, the other half of which is transparent This mirror is rotatably mounted so that its plane of rotation intersects the axial line of the lens at an angle of forty five degrees, and thus during each rotation the light is alternately allowed to strike the film at *C* and then reflected to strike it at *C″* The film guides are so arranged that the exposures at *C* and *C″* are on opposite halves of the width of the film The film is advanced intermittently by two rods *v* and *v′* operated by cranks, the free end of each rod being forked and the tines bent at right angles to engage perforations along each side of the film The forks act alternately so that while the film is being exposed while at rest at one place it is being advanced at the other For projection, a device similar to the camera is used with the addition of two lamps, one in the axial line of the lens opposite *C* and the other at right angles thereto opposite *C″*

The motion picture machine and the phonograph have both reached a high degree of perfection The next step is to connect the two machines so that they will operate in unison Motion pictures unaccompanied by sound give the effect of pantomime On the other hand, the effect produced by the phonograph alone is in many instances as unsatisfactory as the effect produced by a singer or speaker who cannot be seen by the audience The combined effect of motion pictures and phonographic reproduction is necessary to give complete illusion For this purpose substantially complete synchronism between the two machines is necessary in order that each movement shown upon the screen shall be accompanied by the sound originally produced simultaneously therewith Attempts have been made to accomplish synchronism by mechanical connections between the two machines and also by connecting them electrically It is claimed that mechanical connections are not effective since the slightest slip between the parts or any inaccuracy in construction destroys the synchronism As for electrical connections, it has been stated the cost of equipment and maintenance of special electrical apparatus is prohibitive Be that as it may the fact remains that in spite of repeated efforts for a number of years, this feature has not as yet been placed on a practical commercial basis. Mr Edison claims to have solved the problem in his recently exhibited kinetophone, but he is unwilling as yet to publish the technical details of construction The patents along this line are all of rather recent date. The patent to Gaumont, 752,884, February 16th 1904 discloses an example of synchronizing by electrical connections. Referring to Fig 6, the phonograph *L* is driven at a constant speed by any desired motor *Z* The motion picture machine A is driven by a motor which has the coils of rotor *B* connected to a source of electrical energy *I*, while each section of the stator *A* is connected with a section of the collector *C* This latter connection consists of insulated wires formed into a cable *O* Brushes *D* and *E* are rotated around the collector by the gearing *M N* connected with the phonograph The said brushes are connected to insulated rings *e* in contact with brushes *d e*, connected to the two poles of a source of electrical energy *J* When the brushes *D* and *E* are rotated, corresponding polarities are produced in the stator *A*, the law of displacement of which is the same as that of the brushes. Consequently, the rotor *B* will exactly follow the movement of the brushes which are positively driven from the phonograph. In operating this apparatus the phonograph is started with the motion picture machine disconnected. At the exact moment when a pre-arranged signal is given by the phonograph, the motion picture machine is started by means of the clutch *F*

A MAN feels more responsible and self-respecting while attending to a machine than when acting the part of a chambermaid to a horse in a livery stable.

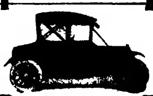
GEORGIAN BROUGHAM PRICE $3,250

EMPIRE BROUGHAM PRICE $2 800

COLONIAL BROUGHAM PRICE $2.375

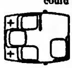


SHELTERED ROADSTER PRICE $2,250

Here is the latest triumph of a company which has originated practically every improvement in electric vehicle construction.

That has factory equipment for the manufacture of every type of electric vehicle, from the smallest runabout or brougham to a mighty five ton truck -

—And whose experience, gained in the making of this unlimited range of elec trics, enable them to evolve this most elegant, comfort able, and convenient of all four passenger electrics.



Without such experience, and the knowledge gained thereby, such an achievement would hardly have been possible

It took the company who built the first coupé electric—the first electric with the high efficiency shaft drive—the first electric which could take either solid or pneumatic tires—the first electric with full elliptic springs and patented drop sill construction—and the first five-passenger full view ahead electric to orig inate and design

The Silent Waverley Limousine-Four

In this wonderful car four sepa rate Pullman chairs replace the usual forward and backward seats. Three face forward, the fourth is a "cosy corner" in front at the right.

Thus affording full four-passenger capacity without obstructing the view of the driver, who sits as usual in the left-hand rear seat—the pleasant and sociable position, with, instead of in front of the other occupants of your car

This arrangement insures ample and delightful spaciousness and absolute freedom from crowding—no crushing of handsome gowns and wraps in the Waverley Limou sine-Four—while permitting of greater luxury and greater elegance than has ever before been possible in a four passenger electric.

The little diagram shows this unique placing of seats, and how golf clubs, parcels, bags, etc., can be stowed out of the way behind the two side chairs. A small item, perhaps, but one that adds greatly to comfort.

Waverley patented drop-sill construction permits of a beautiful, graceful low hung body swung on full elliptic springs as shown in the illustration—a combination which insures easy riding over every road and with any tires while saving current, increasing mileage and protecting your car from racking bumps and jars.

Batteries are flushed from outside the car—no lifting out of cushions with greasy hands, no spotting with water or fabric-eating acids.

The Limousine-Four will be on exhibition at the leading automobile shows, where prospective electric car owners can personally judge of its perfection—

—and decide if such a splendid car the last word in four passenger electrics, could have been designed and perfected except by past masters of electric vehicle construction—men who from long experience know the mechanical requirements of every type, from the most luxurious pleasure car to the massive delivery truck.

Let us send you the Silent Waverley Electric Year Book, which illustrates and describes the Limousine-Four, the famous Limousine-Five and the other Waverley pleasure car models illustrated in the left hand panel.

A beautiful production with decorations by a famous artist—it is yours on request, together with the Waverley Commercial Car Catalog, showing types ranging from a light delivery wagon to a five-ton truck. Address

The purpose of this journal is to record accurately, simply, and interestingly the world's progress in scientific knowledge and industrial achievement

Amend the Panama Canal Act

SUFFICIENT time has elapsed since the passage of the Panama Canal Act last summer for a widespread national discussion of that much debated measure From platform and pulpit, in the magazine and the daily press, the question of free tolls has been so intelligently thrashed out, that the general public or at least the thinking part of it, has to-day pretty well made up its mind as to the wise and just course to pursue in extricating the Government from its present admittedly difficult position

The provision for free tolls, which is the only question in the Act that has been subjected to serious criticism has been attacked on the dual ground of morals and economics. Our objections on the ground of international morality have been clearly stated and are well known to our readers. It is not our purpose to enter into that side of the question again, for we believe that under the new light which has been shed upon the economic side of the question by the report of Prof Emory R Johnson, there will be found ample justification for an amendment of the act so far as the canal tolls are concerned—a procedure which we believe would be in harmony with the present state of public opinion and would furnish Congress with a means of dignified withdrawal from its present debatable position

Without disparaging the weight of the argument based on the moral aspects of the question we believe that the question of tolls will be fought out and finally settled mainly on economic grounds Furthermore, we believe that the Senate in putting the free toll provision into the act was moved thereto by a laudable desire to promote in a just and honorable way, the best interests of American shipping During the months which have intervened since the passage of the Act however two important factors have entered into the problem which to our thinking, have entirely changed its whole aspect These were the publications of Prof Johnson's report on the financial side of the question and the fuller realization of the fact that the leading maritime nations were remitting canal tolls to ships using the Suez Canal, and would probably follow the same course with regard to the Panama Canal

Prof Johnson shows that under existing conditions, coastwise ships sailing between the east and west coasts of the United States are already paying over $4 per ton for the carriage of freight across the Isthmus by the Panama Railroad and doing a lucrative business at that He points out that the payment of the $1.20 per ton toll through the Canal would still leave a wide margin of profit for the coastwise trade. The argument is simply unanswerable It has swept the ground from beneath the feet of those who claim that the tolls should be remitted to coastwise shipping in order to stimulate and develop it The people of the United States thanks to Prof Johnson's analysis, are now perfectly satisfied that the exclusion of foreign shipping from our coastwise trade has given to the latter all the assistance that it can reasonably demand from the Federal Government There is a widespread conviction that to remit the tolls to these ships alone would be to make a gratuitous gift of money from the Treasury to private corporations that stand in no need of it whatsoever

Furthermore there is a growing understanding both inside of Congress and outside, that the repeal of this section of the Act will not prevent the Federal Government from rendering financial aid to the American Merchant Marine should it feel disposed to do so, for, if a flat rate is charged on all shipping, domestic and foreign alike, there will be nothing in the much-disputed treaty with Great Britain to prevent the Government from making a remission of tolls, in whole or in part, to American shipping using the Canal, should it see fit to do so. Obviously, the first step in this policy should be the passing of an amendment to the Panama Canal Act by which its present objectionable feature would be removed.

Two bills for the amendment of the Act are now before Congress, one in the Senate, introduced by Senator Root, the other presented in the House by Representative Simms. Their passage will afford a complete escape from the present *impasse*

It will raise the prestige of Congress to rectify its error by a regular and dignified procedure, which will at once remove the existing misunderstanding with a friendly power and place the Government in harmony with the best traditions of our National policy Furthermore, the passage of these bills will save Congress from the humiliation of having to arbitrate a law which lacks the moral support of the country at large.

Mis-statements in the Oldfield Report

ALTHOUGH no evidence of the actual suppression of inventions was given before the Committee on Patents to which the Oldfield Bill was referred we find in the report submitted by the Committee statements which seek to keep alive that false impression and which are in the main mislead ing Indeed, the Committee was compelled to go outside of the testimony which it took, for proof of suppression In its report it declares "It has been the subject of comment and complaint in the public press for years. Moreover, many instances can be found in the reports of the decisions of the Federal courts"

Quoting from Columbia Wire Company v Freeman Wire Company (71 Fed, 302, 306) the Committee says regarding one of the parties litigant "It has become possessed of many if not all, of the valuable patents for the manufacture of barbed wire and machines for so doing" Examination of the opinion of the court shows, however, that this quotation is merely one clause in a sentence and that the remainder of the sentence and the context flatly disprove every suggestion of suppression either of patents or competition The court really says "It has become possessed of many if not all, of the valuable patents for the manufacture of barbed wire and the machines for so doing and has granted a large number of licenses to persons and corporations under its said patents. The evidence further shows that it has not bound its licensees to any prices, or in any manner limited or restricted their sales or output In other words, there appears to be so far as the complainant's licensees are concerned unrestricted competition in the sale of their products."

The Committee cites a finding of the court in Indiana Manufacturing Company v J I Case Threshing Machine Company (148 Fed 21), but fails to publish the fact that the decision in that case was unanimously reversed by the Circuit Court of Appeals of the Seventh Circuit (154 Fed, 365) So, too, the case of National Harrow Company against Bement (21 A D N Y, 290), a decision by a New York court of intermediate jurisdiction cited with approval by the Committee eventually went to the Supreme Court of the United States, where it was unanimously reversed. (Bement v National Harrow Company, 186 U S., 70)

Contrary to the impression conveyed by the Committee's report the so-called "Lock Case" (Blount Manufacturing Company v Yale & Towne Manufacturing Co., 166 Fed., 555) did not involve the purchase of patents for "purpose of extinction," but raised the question whether an agreement to restrain trade in respect to both patented and unpatented locks was contrary to the Sherman Anti Trust Act, and the court, of course, held that it was. Far from indorsing the objects of the substitute Oldfield bill, the court in this case emphatically dissents from the Committee's position, saying "The right of a patentee to suppress his own rests upon ordinary considerations of property rights. The public has no right to compel the use of patented devices or of unpatented devices, when that is consistent with fundamental rules of property"

The Committee also quotes from the famous "Paper Bag Case" (Continental Paper Bag Company v Eastern Paper Bag Company, 150 Fed., 741; 210 U S., 405), the opinion of a dissenting circuit judge who differed from the majority of his colleagues and from the decision of the Supreme Court of the United States. This the Committee describes as the "best known instance in the reports of suppression of a patent to prevent competition." This assertion by the Committee is important, because in this case, as the Supreme Court pointed out in its decision, we find a clear instance, not of the willful suppression of a patent, but simply of the rejection of an invention, and a use of a better invention accomplishing the same purpose more satisfactorily

The conclusion of the Committee that "these citations are sufficient to show that the practice of buying up and suppressing patents is widely indulged" is wholly unwarranted. The contention that the aggregation of patents under single ownership is a monopoly was disposed of by the Court of Appeals of the Seventh Circuit in one of the very cases relied upon by the Committee (Indiana Manufacturing Company v J I Case Threshing Machine Company, 154 Fed., 365, 371) by the following *reductio ad absurdum* "Their contention comes to this If he owned either alone, over that he would have complete dominion, owning both, he controls nothing The public has no right in either invention, therefore, the public has the right to have them both in the market competing for buyers. Naught plus naught, the sum of the two naughts is a substantive quality"

The value of the "comments and complaints in the public press," which the Committee mentions as proving the suppression of inventions, does not merit serious discussion. Not a single instance of such "comment and complaint" is specified in the Committee's report "I wanted," declared the Chairman, when he presented the report to the House, "to get up as good a report as we could, to make it as plain as possible" Since this is the best showing the Committee can make in respect to suppression of inventions, it is not presumptuous to affirm that present conditions require no change in the patent law upon this point

Modern Psychology

PSYCHOLOGY is the study of consciousness. To-day it is a science, a knowing, but this could hardly have been said of it before our era Psychology is no longer given up to metaphysical speculations, to philosophic inquiry concerning the nature of the soul, the future life, spiritual states, and the like Such are very legitimate considerations, but they have only an indirect and not an essential relation to modern psychology

This science, in the present day sense, originated in the work of Weber and Fechner early in the nineteenth century, but it had no independent standing as a science until 1878, when Wundt (who had his eightieth birthday in August of last year) established his laboratory in Leipzig, where so many "experimentalists," both European and American, have been trained. Prof. G Stanley Hall, in his "Founders of Modern Psychology," considers that "psychology owes to Wundt a debt far greater than to any other man living or dead." Presently Müller, Martius and Ebbinghaus followed Wundt's example in Göttingen, Bonn, and Berlin, respectively within fifteen years sixteen experimental laboratories were established in America, all directed by Americans, except that presided over by Münsterberg at Harvard. And at Harvard the lamented William James prepared his superb treatise, the reader of which readily subscribes to the *mot* that "William James, the philosopher, writes like a novelist, while his brother, Henry, the novelist, writes like a philosopher"

Psychology is now an eminently practical science, and its development has been so great that it has in its turn become divided into branches—or shall we not say distinct sciences. These are the physiological psychologists, who devote themselves exclusively to work upon the anatomy, histology and physiology of the brain, the organ upon which mind is conditioned and in which mind manifests itself most. Then there are the experimental psychologists, who get their data at first hand from study of the conscious, sentient being, human or animal or plant, these experimentalists seek to correct the irregularities and errors of individual observers by objective tests. They eliminate, as far as possible, the personal equation, by the use of accurate instruments in testing data. They deal with a very wide range of problems, as witness one of their meeting programmes. the differential perception of colors in the spectrum, geometrical illusions, the influence of rhythm upon the circulation of the blood, the influence of such substances as tea and hashish on psychic processes; the psychology of the telegrapher; respiration in relation to attention; the development of voluntary motion in the child, the mental faculty and sensation measurements in school children and university students, variation in the nests of the spider; measurements of the variability of instinct; the psychology of the ant queen, the sense and intelligence of the Japanese dancing mouse, etc.

Obviously modern psychology is an important science, because it seeks to measure and to normalize consciousness, that is, psychism or mentality This psychology is really the handmaiden of all the sciences, because all valid scientific conclusions are achieved only through sound mentality.

Engineering

A Turbine- and Reciprocating-engine Competition.—What a fine opportunity for judging the relative efficiency of the turbine and the reciprocating engine was afforded by the recent run of the "Arkansas" and "Delaware" from Colon to Key West at a speed of 18 knots The reciprocating engines of the "Delaware" have some fine records to their credit, and since the "Arkansas" is fitted with the latest type of turbine, the run should afford some excellent and most valuable data as to the relative efficiency of the two types, at least at a speed of 18 knots.

Removing Railroad Grade Crossings.—In view of the growing number of fatalities at grade crossings, the Legislature of New York State should give favorable consideration to the recommendation of the Public Service Commissioner of the Second District that $500,000 be appropriated for eliminating grade crossings of highways and steam railroads. It will surprise some of us to learn that there are at the present time over eight thousand of these crossings in the territory which is covered by the Commission of the Second District alone

Solidifying of the Gatun Dam.—According to that excellent publication, the *Canal Record*, the hydraulically-deposited core of the Gatun dam is now practically covered in by the dry fill. The deposited material is a smooth clay, highly waterproof which has flowed into every interstice in the rock and earth, until the whole mass at the center of the dam has become like a rubble wall, every rock of which is cemented to another This clay is similar to the blue rock found everywhere on the isthmus, and the *Record* states that it is probable that in time the core of the dam itself will solidify into such rock

One-man, Gun-fire Control—The ideal method of firing broadsides from a battleship would be one in which all the guns were given the same training and pointing, simultaneously by one man—provided of course, he is possessed of better training and elevating abilities than the average of the ten or a dozen separate men who do the work at present. Sir Percy Scott has perfected a system by which all the guns can be trained and elevated simultaneously by one man from a given station The latest report states that this method has shown a great superiority in target practice over the old system of separate pointing and training

Large Dipper Dredges.—The excavation of the Atlantic entrance to the Panama Canal called into service dipper dredges of unusual size and capacity The "Mindi" and "Chagres," which are cutting the entrance channel to a minimum depth of 42 feet at mean tide, are working entirely in rock which has been previously broken up, and they bring the material to the surface in 5-yard dippers. The dipper handles are 62 feet in length and the boom supporting the shipper shaft is 50 feet long To facilitate the work the dredges have been equipped with steam dipper trips which have shown good results during six months of work

High-speed Trains in Germany—The 1912 summer-time table of the German Railway Systems, says *The Engineer*, provides an interesting study, for it reveals that a new era of rapid transit has dawned in that country In 1911 a non-stop run from Berlin to Hamburg in three hours and twenty minutes was inaugurated, and in 1912 the run was further accelerated The train left Berlin at 8.55 P M, reaching Hamburg, 178¼ miles distant, at 12:09 A M, the speed being 55 1 miles per hour The return journey was made at 54.5 miles per hour The train was a light one, consisting of four four-axle carriages and a six-axle dining car

Safety Railroading—The Pennsylvania Railroad, co-operating with other lines in the eastern territory, has inaugurated a railroad safety movement, which is the latest move of many made by the company to increase the safety of passengers and employees on its system "Safety First" meetings are to be held in several important centers, in which lectures illustrated with photographs, lantern slides, and statistical tables will be delivered We are glad to note that other leading railroads are moving in the same direction, for we regard this "Safety First" movement as one of the most effective agencies for reducing our present shocking annual railroad list of killed and injured.

The Gas-electric Motor Car—Railway officials have been watching with interest the development of the self-propelled car for use on steam roads. Under steam operation, short branch lines, carrying a limited traffic, are notoriously unprofitable Single units running at sufficiently frequent intervals give a more satisfactory service than the larger once-a-day trains, and the managers have turned to the self-propelled car as offering a solution of the problem. To-day over twenty railroads have self-propelled units of the gas-electric type running on regular local schedule. The consumption of gasoline, while varying with the local conditions, is found on the average to be low, the economy being due to the electric transmission, which lends itself admirably to the particular requirements of local service.

Science

A Yearbook of Agricultural Statistics is the latest periodical publication to be undertaken by that remarkably prolific institution, the International Institute of Agriculture The initial volume, published in 1912, gives statistics for the years 1901 to 1910 from the fifty countries adhering to the Institute, representing practically the whole of the civilized world All the data are from official sources

The Rice-growing Congress—The fourth international congress of rice growing was held at Vercelli Italy, during the early part of November It was decided to establish an international center for rice cultivation and researches upon this subject and accordingly the Vercelli rice-growing plant is to be rearranged and laid out with this end in view The institution will be directed by Prof N Novelli and it is expected to further the interests of this branch of research to a considerable extent

Feeding Plants to Keep Them Warm—It is well known, of course, that human beings and the lower animals are better able to resist cold when they are well fed, but it is interesting to learn that a German investigator has announced that feeding plants has the same effect on them He declares that the introduction of organic substances of nutrient character (carbohydrates, alcohols, acetone) into the plant cell heightens its resistance to cold, even in the case of tropical plants Different substances protect in different degrees The sugars stand highest, then come glycerine, the alcohols, and acetone The removal of the protective contents restores the original degree of resistance

Amundsen Receives a Gold Medal from Peary—On January 11th Capt Roald Amundsen, discoverer of the South Pole, received from the hands of Rear-Admiral Robert Peary, discoverer of the North Pole, the gold medal of the National Geographical Society Replying to the brief speech of presentation, Capt. Amundsen said "Greatly as I am honored by receiving this beautiful medal, I feel that the honor is multiplied a thousandfold by the fact that the presentation has been made by the greatest explorer since Christopher Columbus The desire to search out the South Pole, in fact, the spirit for exploration and discovery was awakened in me by Admiral, then Lieut, Peary whom I met in the Arctic in 1890 "

Right and Left Handed Plants—Do you know that there are right handed plants and left handed plants? An English investigator, R H Compton, has thought the matter curious and interesting enough to make it the subject of extended investigation, and has reported on it to the Cambridge Philosophical Society He observed eight varieties of two-rowed barley to determine the ratio of rights to lefts, in the first leaves of seeds of different varieties and of the various kernels from the same individual spikes, and found that among 12,401 seedlings 7,237 or 58 36 per cent had the first leaf twisted to the left A variety of millet showed an excess of left handed seedlings as was also the case with oats In the case of corn, the ratio was almost unity and there was apparently "no inheritance of right and left handedness as such

The Meteorological Service of Brazil has been completely reorganized and placed under the Ministry of Agriculture, Commerce and Industry of that country About 150 stations are already in operation, and it is planned to greatly increase this number by having each State establish a central observatory and a local network of stations to cooperate with the central institution in Rio Janeiro Several stations will soon be established in the remote interior, at places to which access is slower and more difficult than a journey to Europe At present nine tenths of this vast country is a meteorological *terra incognita*, representing a deplorable blank on the climatic charts of the globe The shining exception to this condition of affairs is the famous coffee-producing State of São Paulo, which has long maintained an excellent meteorological service on its own account The director of the new national service is Prof Dr Henrique Morize

Expedition to the Karakoram.—Dr Filippo di Filippi, well known as an associate of the Duke of the Abruzzi in his mountaineering enterprises, is preparing to lead a scientific expedition to the Western Himalaya and the Karakoram, which will probably be the most important undertaking of its kind ever conducted in that region The proposed route lies from Kashmir over the Himalaya range and through Baltistan and Ladakh into Chinese Turkestan. The problems to be investigated concern topography, geology, gravity, magnetism, and meteorology, including the various forms of radiation and atmospheric electricity The upper air is to be sounded with kites sent up from stations of high altitude—a particularly interesting undertaking, for the reason that the Himalayan explorer will be able to start his kite at a level corresponding to the greatest heights above sea-level heretofore attained by the kite itself in other parts of the world The estimated expense of the expedition is $50,000, of which $30,000 has already been raised

Aeronautics

A New Height Record in an Aeroplane—On January 10th Maurice Chevillard made a new world's record for three passengers He rose to a height of 4,921 feet The ascension was made at Buc, France

A Life Saver for Airships.—Francois Rilleau, of Los Angeles, Cal, has patented No 1 046,023, a safety device for airships in which a collapsible parachute cover is opened by a spring and frames fastened to the airship fold over the parachute cover and are held by a latch to secure the parachute out of operation until necessity for its use arises.

A Novel Envelope for Aerostats.—John R Gammeter, of Akron Ohio has patented, No 1,047 838 an envelope for gas containers, for aerostats, composed of a fabric woven of metallic ribbons and he forms this envelope with a body portion of tightly woven metallic ribbons and with end portions of sheet metal the ribbons being woven so that they present substantially no interstices

Flight Across the La Plata River—A remarkable flight of 120 miles over water was made from Buenos Aires to Montevideo on the 2nd inst by Corporal Fels The distance covered was 120 miles and the time of the flight something over two hours The flight was made down the river which is 80 miles wide at its mouth The young corporal is a student of engineering who is doing one year of military service He pilots a Blériot monoplane

Curtiss Flying-boat for the Army—The flying-boat built by Glenn H Curtiss has been successfully tested at Hammondsport, N Y In the climbing test the machine rose to an altitude of 1 200 feet in 6½ minutes The average speed was 54 8 miles an hour in a 10-mile wind blowing diagonally across the course During a two-hour duration test a total weight of 900 pounds was carried, which included the weight of the aviator and passenger

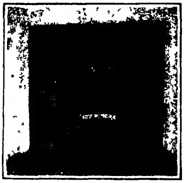
Testing the Twin-engine Principle—According to *Flight*, Lieut Seddon on the Short twin-engine biplane recently rose from Eastchurch to a height of 6,400 feet. Then coming down to 900 feet he cut off one engine, and made a flight of about 9 miles to the south of Sheppey and Leysdown, finishing up with a volplane from 500 feet It has been stated, as a result of this experiment, that should one motor fail at a height of 5,000 feet, the machine would be able to travel a hundred miles without alighting on the water

An Air Scout Killed—According to a dispatch published in the New York *Times*, a war aviator, Dr Jules Constantin with the Bulgarian army was killed in battle On his final flight he left Furna, a small village before the Tchatalja lines, in a biplane, and rapidly disappeared from view When the machine returned and descended, his comrades found him lying dead on the ground with a wound in his chest The wings of his biplane were riddled His barograph showed that he had attained a height of 4 000 feet above the Turkish forts He had just enough strength left to guide his machine toward the Bulgarian camp

Italian Aviation The Italian army is coming to the front in the use of hydroplanes and among other performances we may mention the brilliant flights made by Lieut Ginocchio upon his Paulhan machine at Venice alighting at times amid the numerous gondolas Paulhan, who was on a visit there also made flights before the Italian officers The government is taking up the hydroplane question very actively, and is installing aeroplane posts all along the coast It intends to use Borel hydroplanes quite extensively and has ordered nine of these to be delivered to the Venice arsenal in three months The first hydroplane fleet is now setting out to make over-sea flights, and the pilot Chomet is to make evolutions over the Adriatic On the other hand, the Austrian war department has just ordered one of the newest Paulhan-Curtiss hydroplanes known as "flying boat "

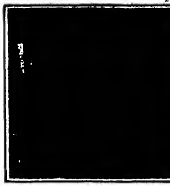
Hydrogen for Military Dirigibles The production of hydrogen for the airships of the war fleet is organized on an extensive scale in Germany All military airship headquarters have their own hydrogen plants located in the vicinity so there are now twelve plants of the kind At Altona near Hamburg, there is a station near the sea coast for airships which are in use with the navy, and the centers of Berlin and Frankfort have each two hydrogen plants Six of the stations lie along the west frontier The new hangar constructed at Frankfort especially for the airship Victoria-Louise" of the Zeppelin type receives hydrogen direct from the Griesheim chemical works by a pipe line 2 7 miles long which is the first of the kind in Europe Using high pressure the delivery of gas per day is as much as 30 000 cubic feet Autogenous welding is used for the pipes so as to prevent any leakage of gas The pipe line ends in a gas holder of 200 000 cubic feet capacity and upon it are eighteen separate outlet taps for taking off gas for the airship's use As these outlets are situated in the hangar itself, it is an easy matter to fill out all the ballonnets of the airship at the same time

Part of a film, showing motions in assembling a braiding machine



The Gilbreth chronometer

At the December meeting of the American Society of Mechanical Engineers a remarkable development in scientific management was disclosed during the discussion of the report of the sub-committee on administration. As will appear from the following article, the development consists in using the moving picture camera to record the number of motions made and the time consumed for each.—EDITOR.



One of the experimental packets.

Micro-motion Study

A New Development in Efficiency Engineering

IN almost every book on efficiency engineering much space is devoted to what is called "motion study." The number of motions made by a workingman or a tool and the time occupied in performing these motions are accurately determined so far as possible. Hitherto the time element has been controlled by means of a stop watch in the hands of a trained observer—no easy task when it is considered that very often hundreds and even thousands of motions and operations must be studied and timed. The more expensive the study, the more likely are errors to creep in.

In order to reduce the labor involved in these painstaking investigations, and above all to eliminate the possibility of error, Mr. Frank B. Gilbreth, a very well known efficiency engineer who has made a specialty of motion study, has invented an entirely new method, which consists in using a moving picture machine in connection with a special chronometer or "clock," as it is termed in the parlance of scientific management.

At the December meeting of the American Society of Mechanical Engineers, Mr. John G. Aldrich of Providence and Mr. Robert Thurston Kent of New York revealed this new method in all its details. So interesting was the subject that it was discussed during an entire session of the Society on a Friday morning and during a supplementary session which lasted until late into the afternoon.

Mr. Gilbreth's special clock makes ten revolutions per minute. Its dial has one hundred divisions, each of which, therefore, represents a time interval of one one-thousandth of a minute.

In studying the motions required to assemble a machine, for example, the chronometer plays as important a part as the object studied. It appears prominently in every one of the hundreds of pictures taken by the moving picture machine. Alongside the chronometer, an ordinary twelve-hour clock, which fixes the time of day, is placed so that in the moving picture film, complete information regarding the time study is included.

Every film reveals the successive positions of a workman in performing each minute operation of the task intrusted to him. The position of the chronometer pointer in successive films indicates the length of time between successive operations. These films are studied under a microscope, and a careful analysis of each operation is made to develop the standard time for each. The interval between the successive films in one study was a little under three one-thousandths of a minute. Obviously such accurate time studies of minute and detailed operations can hardly be made by means of a stop watch. Fine as that study was, it can be made much finer. Chronometers can be used which make one revolution in one thirtieth of a minute, and the dials being divided into hundredths, it is possible to obtain time studies of greater refinement than at present appear necessary. "Micro-motion study" is the name which has been given to this method of recording and studying minute motions or parts of motions. The film is far more than a record of time. In the discussion before the American Society of Mechanical Engineers, it was pointed out that it will serve as an instruction card which may be enlarged and passed from workmen to workmen to teach the best methods of doing work. A film shows a workman not only what to do, but how to do it to the last detail, and, therefore, teaches him what printed instructions and books can never impart adequately. It also shows him the time which the most skilled workingman required for a given piece of work, and which can be equaled if that workingman's motions are mimicked.

Any workman may, for a time, deceive an inexperienced efficiency engineer by "soldiering." But the camera cannot be deceived. The film records faithfully every movement made, and subsequent analysis and study reveals exactly how many of these movements were necessary and how many were purposely slow or useless. Hence by the elimination of the useless movements a most economical method of performing a given piece of work can be attained.

In the Providence works of which Mr. John G. Aldrich is vice-president and general manager, experiments in micro-motion study were made which involved the assembling of braiding machines. Originally the parts were assembled by bringing them to the job in boxes, from which they were taken by the worker, as he required them, and assembled at an ordinary work bench. In transferring the individual pieces to the growing machine many motions were unnecessarily made, all of which were disclosed by the moving picture machine. One result of this micro-motion study of assembling braiding machines was the provision of a bench which brought the top of the completed machine at a convenient level for the workman, and the arrangement of the parts in an orderly manner in bins behind him. Although the number of motions was thus considerably reduced, there were still more than were absolutely necessary. Experience in other trades has shown that it is often desirable to group units composing a single assembly on a "packet" and to arrange them in the order in which they are needed. A similar packet scheme was adopted for the parts of the braider.

The moving picture camera photographing a workingman's motions. Note the clocks.

First a horizontal packet was made up and the motion picture machine disclosed an irregularity and lack of rhythm in the movements of assembling, which seriously cut down the efficiency of the workmen. Then a vertical packet was tried and a standard type of portable assembly bench was thereby indicated. After a few experiments a highly efficient arrangement was devised. The various parts were hung on pegs in the exact position that micro-motion study had revealed as the most economical of motions both as regards time and length of travel. Thus the method permitted the development of the finally accepted method in a small fraction of the time and expense which would have been necessary under the conditions which existed before its invention.

Sawdust Briquettes

A NEW industry may be successfully combined with the planing mills—that of making of the sawdust briquettes to be used for firing under the boilers, thus considerably decreasing the cost of the fuel to the mill owner. This is being very advantageously done in Germany. The sawdust is automatically gathered and conveyed to a place near the presses. From here it is carried over a heated belt-conveyor to a drying room. This is a cylindrical revolving drum about 2 feet in diameter and 20 feet long. In this drum the sawdust is partially dried, the pitch contained in the wood is softened, acting hereafter as a binder. From here the sawdust is conveyed over an incline to the after-dryer of the same shape as the first dryer, which forms a part of the press. Here it is submitted to a higher temperature to drive off all the moisture, and kept running forward toward the end of the after-dryer by rotating paddles. At the end of this after-dryer, the sawdust falls through an opening into the trough of the press, which is a simple angle-lever press. The drive is of the usual shifting belt type, the fixed pulley acting as a flywheel. At the end of each pressing operation, which takes places about 24 times a minute, a briquette is made about 6½ inches by 2¾ inches by 1⅛ inch weighing between one half and three quarters of a pound. From the press the briquettes are carried by another belt-conveyer to a cooling room and are then ready for use. As the installation is very cheap, costing in Germany only $24, it should recommend itself to the attention of sawmill owners, who could utilise to great advantage a heretofore mostly wasted product of their mills.

Russia Forbids Crossing of Frontier in Aeroplane or Airship.—The Russian Cabinet recently issued an order prohibiting foreign aeroplanists and aviators from crossing the western frontier for six months.

Morning and Evening Stars for 1913

Graphic Representation of the Planets and Their Movements During the Year

By Professor Frederic R. Honey, Trinity College

THE changes in the relative positions of the planets as exhibited every year in "Morning and Evening Stars" afford a pertinent illustration that in nature there is no such things as repetition, and while a supreme law pervades and controls every variation in planetary positions, yet each planet yearly occupies a different place in its orbit, and in relation to its fellows, producing conditions which are always unique in planetary combinations. The presentation of "Morning and Evening Stars" thus includes an opportunity to locate each planet, and incidentally to review annually the principal elements of the Solar System.

The Sun.

The sun, whose mass is about seven hundred and fifty times the sum of the masses of all the planets and their satellites, is a sphere whose diameter is 804,387 miles. It rotates on its axis in about twenty-five days in the same direction as that of the revolution of the planets in their orbits. Some idea of the great magnitude of the sun may be obtained by comparing its diameter with that of the moon's orbit, which is 477,702 miles. The sun is the only body in our system whose dimensions would be appreciable in the plot of the terrestrial planets, in which it would be represented by a circle whose diameter is less than one hundredth of the radius of the earth's orbit. At a distance of nearly ninety-three million miles, the sun's diameter subtends an angle of a little over ½ degree. At this distance the prominences which are visible during a total eclipse do not appear—the outline being that of a circle which may be represented to the observer by a disk one inch in diameter at a distance of about nine feet from the eye.

The Planets—Kepler's Laws.

The planets are conveniently studied in three groups—the Terrestrial planets, the Asteroids, and the Major planets. Since the radius of Neptune's orbit is between seventy-seven and seventy-eight times that of Mercury, it is impracticable to represent the orbits of all the planets in one plot. The orbits of the terrestrial planets are drawn to as large a scale as the limits of the page admit, and those of the major planets are necessarily plotted to a scale which is very much reduced. The great difference in the scales is evident by a comparison of the orbits of the earth and Mars in the two plots.

The plane of the ecliptic, which is the plane of the earth's orbit, is represented by this page, which for convenience of reference may be placed in a horizontal position. A planet may be described as above or below this plane, but it should be understood that this description is simply to aid the imagination, since there is no such thing as horizontal and perpendicular, or above and below in stellar space.

The planes of the orbits of the terrestrial and major planets form small angles with the plane of the ecliptic. The intersection of the plane of a planet's orbit with the ecliptic is the line of nodes, and the point N where the planet passes from the space below to that above the ecliptic is the ascending node. N′ is the descending node. Perihelion or point of nearest approach to the sun is at P.

The Terrestrial Planets.

MERCURY

On account of the great eccentricity of the orbit the planet illustrates more vividly than any of the terrestrial or major planets the first two of Kepler's laws of planetary motion: 1. The orbit of each planet is an ellipse with the sun at one focus. 2. The radius of the orbit sweeps over equal areas in equal times. The center of Mercury's orbit is at b at a distance from the sun of a little over one fifth of the mean distance between the sun and Mercury, and the area of the triangle with that part of the orbit between the positions at the dates August 22nd and August 30th with the sun as a vertex is equal to the area of the triangle with the same vertex and a base equal to that part of the orbit between the dates October 1st and October 9th. The planet accomplishes its revolution in very nearly 88 days (87.97), and the positions are shown at intervals of two days. In order to avoid confusion the date is attached only for every eighth day. Mercury's orbit is inclined to the ecliptic at an angle of 7 degrees. The mean distance from the sun expressed in terms of the earth's mean distance is 0.3871, the period (88 days) 0.2408, and $0.3871^3 = 0.05798 = 0.2408^2$ illustrating Kepler's third law, viz.: The squares of the periods of any two planets are proportional to the cubes of their mean distances from the sun. The orbital velocity of the planet is subject to great variations. At perihelion it moves at the rate of 35 miles a second; at aphelion the velocity is reduced to 23 miles a second.

VENUS

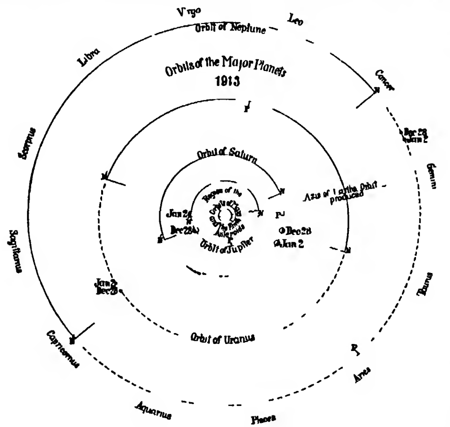
The eccentricity of the orbit is less than that of any of the terrestrial or major planets, its linear measurement being so small that it is scarcely visible in the plot. As a consequence Venus moves in a very nearly circular orbit at an almost uniform velocity of 21.9 miles per second. The plane of the orbit is inclined at an angle of nearly 3.4 degrees, and the planet's mean distance from the sun is equal to 0.723 times the earth's mean distance. The period of revolution is 224.7 days, and the position of Venus is shown at intervals of four days. On August 14th the planet very nearly reaches the position of January 2nd. The distance between these positions is that traversed in seven tenths of a day. The dates for the first revolution are attached without the orbit, those for the second revolution within the orbit.

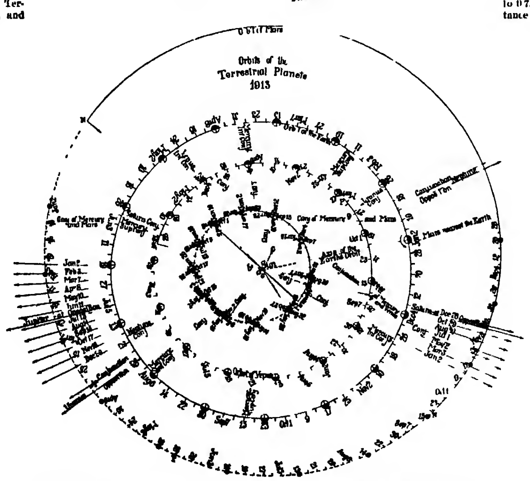
THE EARTH

The center of the earth's orbit is at a. Its eccentricity, c, representing a little over 1½ million miles. Thus in January our planet approaches more than three million miles nearer the sun than in July. At a mean distance from the sun of 92,894,767 miles the earth performs its revolution in 365.25 days at a mean velocity of 18.5 miles per second. The positions are shown at intervals of four days.

MARS

The great eccentricity of the orbit brings the center c at a distance from the sun equal to nearly one tenth of the mean distance of the planet. The plane of the orbit is inclined at an angle of 1.85 degrees. At a mean velocity of 15





ORBITAL MOVEMENTS OF THE MAJOR AND TERRESTRIAL PLANETS FOR 1913.

miles per second, and at a distance equal to 1.5237 times the earth's mean distance, Mars completes a revolution in 1 88 years. The positions are shown at intervals of four days.

The Asteroids.

For the purpose of this article it is not necessary to do much more than refer to these fragmentary bodies occupying the space between the orbits of Mars and Jupiter The elements of the orbits of seven hundred and fourteen of the planetoids have been tabulated, and the number is continually increasing Some of the orbits show great eccentricity, and are inclined at large angles to the ecliptic The distances of four of the most remote of these bodies do not differ very much from Jupiter's distance, and the orbit of Eros, whose period is even a little less than that of Mars, on account of its great eccentricity, comes very near the earth's orbit.

The Major Planets.

JUPITER.

At a distance from the sun equal to 5.2 times the earth's mean distance, Jupiter makes a revolution at the rate of 8.1 miles per second in 11.86 years. The eccentricity of the orbit, which is inclined at 1.3 degrees to the ecliptic, is a little over one half that of Mars. The direction in which the planet would be seen from the sun is shown in the plot at intervals of 32 days.

SATURN

Saturn's orbit, which is inclined at 2.5 degrees, shows a greater eccentricity than that of Jupiter The ringed planet's distance from the sun is a little over nine and a half times the distance of the earth, and its revolution around the sun, at a velocity of six miles per second requires 29 46 years.

URANUS.

The orbital eccentricity of this far distant planet is very nearly equal to that of Jupiter, but on account of its remoteness from the sun (which is 19.19 times the earth's distance) the linear eccentricity, or actual distance from the sun to the center of the orbit, is nine tenths the earth's orbit radius. The inclination of the orbit is only ¾ degree, less than that of any of the orbits of the terrestrial or major planets. At a velocity of 4.2 miles a second, Uranus completes a revolution in 84 15 years.

NEPTUNE.

The outermost planet, whose distance is 30 07 times the earth's distance, has a velocity of 3.4 miles per second, which on account of the small eccentricity is nearly uniform. The orbit is inclined at an angle of 1 76 degrees, and the period is 164.79 years. In common with all the planets Neptune conforms to Kepler's three laws of planetary motion.

Conjunctions and Oppositions.

The positions of the planets are shown in the plots at Greenwich noon The hour of the day when a conjunction or an opposition occurs is indicated by the measurement on the orbit.

TABLE I.—GREENWICH TIME.

Date.		Conjunctions.	Oppositions.
January	14		Neptune
January	23	Uranus	
February	12	Mercury (sup.)	
March	27	Mercury (inf)	
April	24	Venus (inf)	
May	20	Saturn	
June	1	Mercury (sup.)	
July	5		Jupiter
July	18	Neptune	
July	28		Uranus
August	4	Mercury (inf.)	
September	16	Mercury (sup.)	
November	22	Mercury (inf)	
December	6		Saturn

Mars comes nearest the earth on December 31st, but the planet will not come to opposition until January 5th, 1914, when on account of the eccentricity of the orbit, Mars will be a little farther from us.

Conjunctions of the Planets.

Twelve conjunctions of the planets occur during the year Only two are illustrated—those of Mars and Mercury, and of Mercury and Venus. The others may be discovered by the reader with the aid of a straight edge, which should be applied to the earth and the planets at the dates given in the table.

TABLE II.

Date		Planets.
January	9	Mercury and Mars
January	11	Mercury and Jupiter
January	13	Mars and Jupiter
January	31	Mercury and Uranus
February	25	Mars and Uranus
May	8	Mercury and Venus
May	31	Mercury and Saturn
June	23	Mercury and Neptune
July	21	Venus and Saturn
August	24	Mars and Saturn
August	20	Venus and Neptune
December	2	Mercury and Venus

How to Find Morning and Evening Stars.

Place the accompanying plot of the terrestrial planets in such a position that the earth at the assigned date is between the reader and the sun. The dates attached to the earth, Mercury, Venus and Mars, may then be seen without turning the head. A straight-edge passed through the earth and the sun will divide the planets into two groups. Since the earth rotates in the directions of the arrow (see position for January 2nd) the observer emerges at sun-rise from the shadow area, and the planets on the right rise before the sun and are morning stars. At sun-set the observer enters the shadow area, and the planets on the left of the plot as inspected, set after the sun and are evening stars. Between inferior and superior conjunctions Mercury and Venus are morning stars, and between superior and inferior conjunctions these planets are evening stars. Before conjunction a planet whose orbit is outside the earth's orbit is evening star, after conjunction it is morning star When a planet is at opposition it is above the horizon before and after midnight, and is both morning and evening star Following this method the morning and evening stars for any day of the year may be ascertained.

The New York Automobile Shows

NOW that the Selden patent is a thing of the past, the two big automobile shows which have generally been held heretofore by rival interests were this year—the thirteenth of these exhibitions—conducted under one management. The National Association of Automobile Manufacturers spared no expense to make the 1913 shows the best yet, and in the Grand Central Palace show so elaborate were the decorations that the walls were covered with specially painted woodland scenery

Practically all the cars exhibited this year have two distinct improvements—motor starters and electric lights. The self starters are of several kinds, ranging from a coiled spring to acetylene gas, which is pumped into the cylinders and exploded by a spark, but the most popular device of this kind at present is the electric, in which a small electric motor placed beside the flywheel carries a pinion that can be meshed at will with teeth cut on the periphery of the wheel. Current from the 6-volt or higher storage batteries, drawn at the rate of 150 amperes or more for a few seconds, causes the motor to make the few revolutions sometimes necessary to start it. This current is restored to the batteries later by the motor acting as a dynamo, or by a separate charging dynamo used on some systems.

By far the neatest electric self-starter consists of an 8-pole ring-armature motor, the armature of which forms the flywheel of the gasoline engine Thus the hundred pounds or more of extra dead weight is eliminated. One starter has the electric motor mounted in front of the radiator and driving the crankshaft through a worm gear Another consists of an opposed cylinder air motor similarly situated. But as a rule the mechanism is concealed, and the only indication that a car is so equipped is a cap on the end of the crankshaft. This can be unscrewed and a starting crank applied if for any reason the self-starter fails.

Given a charging dynamo, the installation of an electric lighting system is an easy matter Electric headlights are more powerful than acetylene lamps, besides giving a perfectly steady and white light. The tungsten filament lamps are also economical of current, which is generally supplied by a 6-volt storage battery The Westinghouse system makes use of the frame of the car in place of a return wire, thus cutting in half the amount of wiring and simplifying greatly the detection of any trouble. Closed cars are fitted with dome lights in the ceiling, as well as with interior antique lanterns in some instances. Many have dashboard lights to illumine the various meters and gages at will, and in one instance the push switches for all lights were arranged on a panel just below the steering wheel. In the majority of cars, the usual side lamps are dispensed with and two bull's eye electric lights are placed in the dashboard.

The upholstery on the 1913 cars is better than ever before, the cushions are thicker, and everything has been done for comfort. On some high-priced cars cushions 10 and even 14 inches thick are used.

Shock absorbers are fitted to a few machines, but they are not part of the regular equipment as a rule. There have been one or two new types of springs introduced, but no maker has adopted a substitute for springs such as the Cox pneumatic cushion described in these columns some time ago.

Several makers have returned to the use of wire wheels, which, it will be recalled, is the type that was used on the first automobiles. An English wire wheel that has met with success in Great Britain has of late been applied to a number of American cars. Wire wheels are rather more elastic than wood wheels, besides offering the advantage that they can be readily repaired, even when badly damaged.

Rounded or pointed radiators have been adopted by a few more concerns on their 1913 product. They give a car a "speedy" appearance besides being stronger and having more radiating surface.

As regards engines, there were practically no novelties. Two or three firms exhibited cars equipped with the Knight sleeve-valve motor, and a sectional engine was shown in operation. Only one car still uses an air-cooled motor The vertically flanged cylinders are jacketed and air is drawn down through the flanges by means of fan blades in the flywheel. Another car is fitted with a rotary valve motor such as has been previously described in our columns in connection with aeronautic engines. The 6-cylinder engine, though not quite as prominent as it was last year perhaps, is nevertheless manufactured by most of the leading automobile builders, and can be had at a little higher price than the four For car prices we refer our readers to the table on page 44 in our recent automobile number of January 11th.

Electric pleasure vehicles were crowded out of the Madison Square Garden show this year completely, and only a few makes were shown at the Grand Central Palace Noteworthy among these was a brougham which climbed Mt. Wilson in California, a height of over a mile above the sea This machine is equipped with a lead battery and covers 75 miles on a charge on good roads. In the commercial vehicle shows to be held in the Garden and Palace from the 21st to the 26th inst., doubtless electric automobiles will figure more prominently

The Transportation of Live Fish in a Frozen Condition

FISHES belong to the class of animals that have variable body temperature, depending on the temperature of their environment. In extreme cold they assume a rigid condition, in which all of the vital functions are suspended, while life still remains present. During several months of each year some of the great rivers of Siberia are frozen solid to the bottom but many of the fishes imprisoned in the ice retain their vitality, and resume their active life when the ice melts in spring.

This fact has suggested experiments in the freezing of live fish for transportation, which are discussed in the *Fischerei Zeitung* Many years ago the celebrated physicist Pictet of Geneva put fresh water fishes into a tub of water, which he kept liquid at the freezing point for 24 hours, and then allowed to freeze slowly into a solid block of ice, which afterward was cooled gradually to — 20 deg. Cent. (—4 deg. Fahr) When the ice was melted, a month or even two months afterward, the fishes began to swim as briskly as they did before freezing, and showed no symptom of ill health.

Similar experiments have recently been made in France. The fishes are placed in water which is kept near the freezing point for a few hours, then at the freezing point for 15 to 18 hours, and finally frozen by immersing the vessel into a freezing mixture, producing a cake of ice a few inches thick, in which the frozen fishes are imbedded. This cake is wrapped in cloth and surrounded with a heat insulating packing to prevent melting during transportation. It is necessary to thaw the ice very slowly and to keep the water near the freezing point for several hours, in order to preserve the life of the fishes. Even those which do not survive are in a perfect state of preservation.

The Death of Dr. Thaddeus S. C. Lowe

AT the ripe age of eighty Dr Thaddeus S C. Lowe died on January 16th at Pasadena, Cal. He was a type of brilliant all around inventor and engineer that is fast disappearing. He worked in many fields, usually with conspicuous success. Probably he is best known for his remarkable improvements in water gas apparatus which were adopted generally So, too, his inventions relating to artificial refrigeration, metallurgical furnaces and coke ovens earned for him fame and fortune. Even aeronautics received his attention; for he was chief balloonist of the Union army during the civil war. Indeed, his early exploits in ballooning were remarkable. He rose to a height of 23,000 feet in 1858 and in 1861 he drifted 900 miles in nine hours The observatory at Mount Lowe in California was built by him.

How to Remove Old Wall Paper

A GOOD way to remove old wall paper is to use the following solution: A thick pasty solution should be made by adding flour and a few spoons of salt into boiling water. After this is made add a few ounces of acetic acid, which may be purchased at any drug store. This pasty mixture should be applied with a brush to the old wall paper [illegible] few minutes the old paper [illegible] [illegible]

Attitude of Railroads to the Automatic Stop

To the Editor of the SCIENTIFIC AMERICAN

Your editorial on "The Automatic Railroad Stop" in the issue of December 28th last, as well as the several articles which you have recently published on automatic train control, have proved of much interest to those concerned in railway operation.

It is a sad commentary on the intelligence of railway managers when a large reward is offered through a displayed paid advertisement, coupled with conditions that savor of an attempt to make the public believe that from a high motive and in the interest of the traveler, the railroad is seeking safety devices which have never been heard of before, as well as to make it appear that to railroad managers such devices are an unknown quantity, and that a reward advertising the road is the only means necessary to encourage the invention of some device to overcome the "human equation."

But the facts remain, that for a long period of years such devices have been exploited, tested, and published, and those interested have been afforded opportunities for investigation, if they desired to do so. It is well known that automatic stops were in service on the Chicago elevated roads before the Boston elevated road was built or even contemplated, automatic stops were used in connection with interlocking and yard signals on the Boston, Revere Beach & Lynn Railroad in 1891, the intramural railway at the Chicago World's Fair in 1893 was equipped with a complete system of automatic block signals and stops, and attracted much attention from railroad managers. In the winter of 1893-4 the Chicago South Side elevated road installed station protection, consisting of signals and automatic stops, and in the winter of 1894-5 the Metropolitan West Side (elevated) road of Chicago installed block signals and automatic stops.

That the subject is not a new one, we refer to the SCIENTIFIC AMERICAN, which nearly twenty-three years ago—to be exact, on May 10th, 1890—on their front page gave illustrations and described a system as follows

"The Rowell Automatic Railway Safety Stop"

"We had the pleasure of attending a thorough test made of the Rowell safety stop given at Neponsett, Mass., on April 9th

"A special train of four cars was run from the Old Colony Depot in Boston, and a large number of prominent railroad officials were among the guests. Several tests were made, all of which were successful and conclusively showed that with the safety stop in position, it was possible to stop a train running at the rate of 40 miles an hour in less than 500 feet.

"In the first test the train was stopped in 380 feet, second test was made in 390 feet, and in the third test, made with all the party on board, the train was stopped within 370 feet, and the shock, though plainly felt when the brakes were applied, did not inconvenience anyone All present pronounced it an unqualified success, and tests were also made with the portable form of safety stop, which enables the conductor to absolutely prevent his train from being run into from either direction

"Safety Stop.—The effectiveness of this device does not depend upon the speed of the train. It stops the train without the aid or knowledge of the engineer, who can by this absolute protection maintain a high rate of speed on the darkest night, when it is impossible to see the signals.

"B C Rowell, the inventor, is an old railroad man, having been for many years brakeman and conductor, and thus has a practical knowledge of exactly what is of use in an emergency

"This safety stop, while absolute in the protection afforded, is comparatively inexpensive, certain in action, and easily applied. Its general adoption by the roads would greatly lessen the danger of travel and entirely do away with nine tenths of the accidents that are so costly to the companies."

On April 3rd, 1909—nineteen years later—the SCIENTIFIC AMERICAN SUPPLEMENT had an illustrated article on the front page, written by Frank G. Perkins, describing the same invention, further developed, which was installed on the main line of the Chicago, Burlington & Quincy Railroad, and under Government test, as a complete system of automatic train control to meet all operating conditions.

It is not necessary to enumerate the individual tests under the supervision of the Block Signal and Train Control Board during their existence and covered in their printed reports of 1908, 1909, 1910, and 1911, which reports were largely distributed, as many as 5,000 copies of their second annual report (November, 1909) and [illegible] copies of their third annual report (November, 1910) having been distributed from their secretary's office.

The Board was abolished [illegible] under a joint resolution of Congress approved June 30th, 1906, "to enable the Interstate Commerce Commission to investigate in regard to the use and necessity for block-signal systems and appliances for the automatic control of railway trains, including experimental tests, at the discretion of the Commission, of such of said signal systems and appliances only as may be furnished in connection with such investigation free of cost to the Government in accordance with the provisions of the joint resolution approved June 30th, 1906." Owing to the large number of devices submitted, the Board informed the inventors that "their ideas cannot be considered unless presented in the form of plans and specifications showing in detail a practicable device designed to perform a useful function, and clearly describing the manner in which that function is proposed to be performed" Only such devices were approved as were considered as possessing merit to warrant the Board in offering to test satisfactory installations.

According to the Board's fourth annual report (December, 1911) the last report issued, a total of 21 automatic train control devices were upon examination considered to possess sufficient merit to warrant the Board to test satisfactory installations. Illustrations of these devices with full description and record of tests under all weather conditions can be found in the Board's reports.

In the fourth annual report the Board states

"The information obtained from tests, together with knowledge of the general state of development of the art of automatic train control, leads the Board to conclude that there are several types of apparatus and methods of application which, if put into use by the railroads, would quickly develop to a degree of efficiency adequate to meet all reasonable demands. Such devices properly installed and maintained would add materially to safety in the operation of trains. In many situations, under conditions existing in this country, the Board is convinced that the use of automatic train stops is necessary to the safe operation of trains

"Further, the Board has no hesitancy in saying that had the railroads directed the same effort toward the development of automatic train-control apparatus that has been devoted to the development of interlocking and block-signaling apparatus, we should now have adequate installations of automatic train-control devices which would permit an engineman to handle his train without interference as long as he did it properly, but would intervene to stop his train if he disregarded a stop signal or ran at excessive speed where speed restriction was prescribed."

To ignore these reports because the Board have not designated some one particular device is unjust, as the province of the Board was to report on the good and bad features of each device under test. The Board in their fourth annual report state

"This Board can do no more than render an opinion concerning the devices examined, and when favorable opinions are rendered, it has only the effect to enable the proprietor of the approved device to advertise more extensively"

The statement that "when favorable opinions are rendered, it has only the effect to enable the proprietor of the approved device to advertise more extensively," is not in conformity with the scientific treatment of an important subject by a body of experts or to be used to cloud their findings. The installations being made at the owner's expense, should not be deprived of a favorable report if the device merited one, as well as all other advantages resulting therefrom.

The railroads have the benefit of five years of Government investigation at the expense of the proprietors, the experimental stage has been passed. There would be no difficulty, if there was a disposition in finding appliances that will meet all conditions of automatic train control Many of the objections raised are theoretical from lack of practical experience, but in justice to the railroads, and possibly overcoming one of the most serious objections on their part, they should be protected as outlined in the third annual report of the Block Signal and Train Control Board, viz.

"One objection which has been urged against the introduction of new safety appliances is that after a partial introduction of them, a liability for damages might exist in connection with accidents on part of a railroad not yet equipped with them. It has been suggested that such a situation might be met and the objection entirely overcome, so that no injustice would be done to the railroad, by a simple enactment that the partial application of such devices should not of itself create any legal obligation to equip the entire line in the same manner, that such fact should not be admitted as evidence in any court of an obligation to equip any part of a road not already equipped, and that any case of damage occurring on any portion of a road not equipped should be determined without consideration of the installation on another part of the road."

Protection should be given the railroads when they equip a portion of their road for experimental purposes or by compulsion Such enactment would undoubtedly remove much of the prejudice now existing, and would tend to promote the development of all kinds of safety appliances. GEORGE W RISTINE

Chicago, Ill.

Turning Effects of Rudders

To the Editor of the SCIENTIFIC AMERICAN

My attention was drawn to a correspondence in your issue of Jnly 13th last, by Mr A C Lawrence of Toronto, a copy of which I beg to inclose and which I think much to the point Why, indeed, should autos be steered from forward, making every turn with a surprising neatness, and a ship twenty times as long as an auto be steered like the wheelbarrow, from behind?

I hereby beg to inclose a set of drawings which, if you compare them with Mr Lawrence's letter, will express to you my opinion on the matter

In the drawings of three ships, Fig C corresponds with Mr Lawrence's explanation of the stern rudder action, and Fig A with his explanation of the bow rudder action Fig B shows the movement of a ship under the combined control of both bow and stern rudders I send you, also, the necessary details for a bow or forward rudder such as I have tried, for twelve years, to make the people on this side of the Atlantic to see the use of

If you, Mr Editor, would convey a great boon to seafaring men all over the world, publish the inclosed drawings with such editorial remarks as will seem proper to you A H KIEHL.

Voorburg, near The Hague

[Our correspondent sends us also sketches of his design for a balanced bow rudder, carried in the forefoot between the stempost and keel and an inner 'cage' stempost The bow rudder is in use on special types of vessels, particularly on ferryboats, the practice being common in American harbors. It would greatly facilitate the quick avoidance of near objects Structural objections have prevented its adoption on large ocean steam ships.—EDITOR.]

Free Will Versus Determinism

To the Editor of the SCIENTIFIC AMERICAN

I was glad to see Mr Agnew's able letter in your issue of December 21st, 1912, supporting man's free will against the shallow, fatalistic theory of the determinists.

No one with any pretensions to enlightenment upholds the latter nowadays. Instead of determinism being the "only thoroughly scientific standpoint," it is merely a relic of the materialistic thought of the 19th century

Man is not a mechanical automaton, but a spiritual being—a living soul—inhabiting a physical body for temporary purposes, and when he realizes this, and in right of this, he is able to rise above all external forces and limitations.

All of the great thinkers are in favor of free will under certain restrictions, of course, the greatest of all, Kant for instance, with his "You can because you ought." Capacity goes with obligation Freedom is the fundamental presupposition of all morality

Some of the leaders of the materialistic theory have lately acknowledged that behind the laws of nature there must be a Law-giver, thus practically giving their whole case away

Should any of our readers be still in doubt on the point, let them read Bergson's "Time and Free Will," where the problem is thoroughly thrashed out Indeed the controversy is a futile one, arising from a mistaken conception of terms and a lax way of thinking about time and space—a desire to endow duration with the attributes of extensity As Bergson puts it "Every demand for explanation in regard to freedom comes back, without our suspecting it, to the following question Can time be adequately represented by space? To which we answer, Yes, if you are dealing with time flown, No, if you speak of time flowing Now the free act takes place in time which is flowing, and not in time which has already flown Freedom is therefore a fact and among the facts which we observe there is none clearer". A. K VENNING

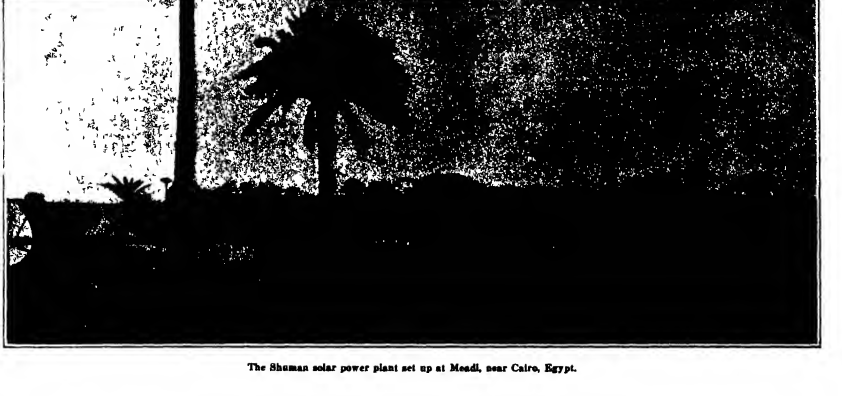
[The Editor can publish no more letters on this subject.]



The Shuman solar power plant set up at Meadi, near Cairo, Egypt.

An Egyptian Solar Power Plant

Putting the Sun to Work

IN the SCIENTIFIC AMERICAN of September 30th, 1911, we described and illustrated the solar power plant which Mr Frank Shuman of Philadelphia designed for eventual use in Egypt The plant was actually transported to Egypt and there set up but in slightly modified form

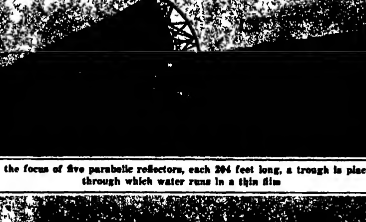
It will be remembered that instead of employing lenses or mirrors as Ericsson did, to concentrate upon a small boiler the heat rays of the sun, Mr Shuman utilizes a heat absorber which may be likened to a greenhouse In the Philadelphia plant a thin film of water flowed over the bottom of a trough inclosed by two layers of glass between which was an airspace Plane mirrors at each side of the trough reflected additional rays of the sun upon the water The trough was carefully insulated In this absorber the water was raised to a temperature very nearly that of the boiling point of water To utilize the heat energy thus stored up, Mr Shuman had to devise a special low pressure reciprocating steam engine The heated water which is utilized was returned to the absorber after having performed its duty

In the Egyptian plant Mr Shuman used parabolic instead of plane mirrors, with better results All told five absorbers and reflectors were installed at Meadi, a suburb of Cairo Each reflector parabolic in form was 204 feet long and in its focus was the trough Silvered glass mirrors lined the sides of the reflector and constantly faced the sun The troughs of all five reflectors were rectangular in section 14 inches wide with sides only three inches apart In order to increase the heat absorbing efficiency the troughs were painted black

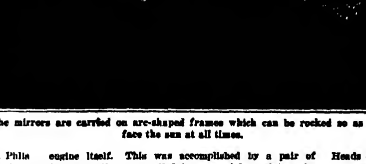
The glass plates and insulating material employed in the absorber of the Philadelphia plant have been discarded The steam is collected at one end in a pipe four inches in diameter and the water flows in at the other end. Between the water and steam ends there is a drop of six inches in the entire length of 204 feet of the absorber The engine presumably is the same as that which was used in Philadelphia It works at somewhat below atmospheric pressure or at a pressure corresponding with a temperature of about 200 deg Fahr Connected with the engine is a condenser of the ordinary type and auxiliaries, such as may be found in many a condensing plant The vacuum to operate the condenser is obtained before starting by means of a gasoline-driven air pump. After the plant is in full operation the gasoline engine is cut out

In order that the reflectors may be cleaned—an operation more or less frequently necessary because of the dust prevalent in Egypt—the mirror frames can be tilted and the mirrors washed with a hose.

In the Philadelphia plant the troughs were mounted on supports which elevated them some thirty inches above the ground and which permitted them to be inclined perpendicularly to the sun at the meridian These adjustments of the installation were made about once in three weeks. In the Egyptian plant the reflectors were made to follow the sun automatically through out the day by gearing them up with the main steam engine itself. This was accomplished by a pair of friction pulleys controlled by a special regulator, the chief element of which was a thermostat



In the focus of five parabolic reflectors, each 204 feet long, a trough is placed through which water runs in a thin film



The mirrors are carried on arc-shaped frames which can be rocked so as to face the sun at all times.

Instead of twenty-six rows of absorbers the number used in the Philadelphia plant, five only were installed in Egypt, so placed that one could not shade the other

The Egyptian plant was started with zinc boilers or absorbers. A temperature so near the boiling point of zinc was reached that the troughs finally hung down limply like wet rags. Although hard solder was employed, it melted down at the top of the absorbing troughs. For all that Mr Shuman assures us, the zinc absorbers lasted long enough to prove that the plant might be eventually successful He claims to have found that water can be pumped for less than one third of the price which would have to be paid if coal were burned. A set of steel troughs is now in course of construction, which will probably be installed in about four months. By welding the joints with the oxy acetylene flame he hopes that they will be absolutely indestructible.

Mr Shuman states that the steam pipes are so long that the steam becomes highly super heated where it issues near the engine

Up to date something like one hundred thousand dollars have been spent on these experiments.

The Art of Primitive Man

OUR far-off ancestors of the stone age, the rude and primitive men of the quaternary epoch to whom the use of fire was unknown and whose arms consisted of a few roughly hewn pieces of flint, nevertheless appear to have had some rudimentary artistic ideas. In fact, sculptures dating from 200,000 years were shown at the last congress of prehistoric archaeology and anthropology, which recently held its fourteenth meeting at Geneva This subject was treated by a French scientist, M Dharvent, of Bethune, and he showed specimens of sculptured silex representing animal figures which were found in the alluvial strata of the quaternary epoch among arms and instruments of the same period. M Dharvent made an interesting communication to the congress about these first trials at sculpture which have yet been discovered. Natural stones were used which had some resemblance to animal figures, and these were afterward retouched so as to finish the work One of the striking specimens is the head of a monkey, in which the features are very clearly seen, especially when viewed in profile, as the photographs show We hope to be able to obtain views of these specimens in the near future. Heads of other animals and birds are also among the most remarkable specimens. Authorities on prehistoric questions consider that the strata bearing these finds date from about 220,000 years.

A Massive Rudder.—What is believed to be the biggest rudder ever made in two pieces, the top portion weighing 27 tons and the bottom portion 15 tons, has been built for the new Allan liner "Calgarian," now under construction at Glasgow. The total height of the rudder is 26 feet 6 inches and the extreme width is 21 feet.

The exhaust machine and whistle is driven by a motor. One machine is used for the train and one for the automobile.

"The Whip" and Its Mechanism

A Ponderous Melodrama with Dogs, Horses, Automobiles and Trains that Move and are Wrecked

Back of the car, showing motors for driving false wheels, raising and rotating the panorama Note the steam exhaust

"THE DRURY LANE," with its massive melodramas, is a household word among all English-speaking people. The stage of this theater, with its huge electrically-driven bridges, lends itself to effects requiring ponderous machinery and accessories. One of the best plays ever put on at the famous London playhouse was "The Whip," which ran continuously for two years, delighting hundreds of thousands. This production has now been translated bodily to the Manhattan Opera House, New York There are four acts and thirteen scenes in the play but we need concern ourselves only with two, which are interesting from a mechanical point of view These are the famous rail road wreck and the horse race, both of which are now illustrated for the first time by authoritative photographs and drawings.

The entire play is written around "The Whip," a race horse of phenomenal speed, on which large sums of money are wagered. This forms the motive which leads to the perpetration of an atrocious crime The race is supposed to be run at New market for the '2,000 guineas' stakes. This necessitates the transportation by rail of "The Whip," with her trainer and jockey, in a box car, such as we so often see attached to English local trains. One of the prettiest scenes is that where the race horse is led to the Falconhurst Station and loaded on the waiting box car Presently you hear the sound of the whistle, the friction of revolving wheels and the exhaust of steam, and a regular English coach, with four compartments, comes slowly down the track and picks up the box car The signal to start is given the wheels revolve, the country flashes past. After a few minutes a tunnel is reached, and the audience can even see the bricks as the train rushes through it This is the opportunity which the villain has been waiting for, the death of the mare must be accomplished at all hazards. He opens the door of his compartment crawls along the running board throws off the tail light on the box car and uncouples the car, leaving it standing on the track, while the train passes out of view of the passengers.

The box car containing "The Whip" leaving Falconhurst Station

The heroine finally succeeds in reaching the tunnel by automobile just in time to release the horse and the jockey the trainer having been detained by a misadventure in Madam Tussaud's "Chamber of Horrors." They make frantic efforts to flag the express, which is heard approaching at a rapid rate of speed The engineer fails to stop in time and the locomotive strikes the box car, which is converted into kindling wood There are many passengers on the express train killed and wounded The steam and fire effect at the locomotive is very realistic.

Now, let us explain how it is accomplished. The coach is operated by about eighteen men, who control the various switches and force the car back and forth attend to the exhaust to the whistle and to the management of the panoramas Only three men can be shown at the back of the coach, otherwise the machinery would be obscured There is a set of false wheels in front which do not run on the track, but mask the actual wheels. An electric motor serves to operate them motion being transmitted from the rear of the coach to the false wheels by the aid of shafts. There is another motor which raises the small panorama at the back of the coach which serves to simulate the bricks in the tunnel A third motor is for the purpose of driving this panorama widthwise The electric lights in the coach go out for an instant when the panorama is raised The effect of the exhaust steam from the locomotive is obtained by using a jet of steam illuminated from a spot light and working intermittently A simple exhaust throttle valve controls this jet It is started by hand and when the speed of the train is to be increased a motor is thrown in. The whistle is carried on the same framework and is blown at the time of starting and stopping A simi

(Concluded on page 107)

Climbing a Magnetically Supported Chain

By Our Berlin Correspondent

AN interesting experiment was recently made at the works of one of the large German manufacturing firms with one of their lifting magnets. A chain secured to the ground at one end and carrying an iron ball at its free end was raised to a vertical position by the approach of the lifting magnet suspended from a crane.

As seen from the accompanying photograph the chain throughout its length remained in vertical position below the magnet. A grown up workman climbed up the chain without disturbing its rigidity. The chain seemed to float in air. The magnetic pull on the ball was greater than the gravitational pull on the man.

This remarkable experiment shows the enormous power of attraction exerted by industrial lifting magnets as used on an ever increasing scale in iron and steel works for the transport of iron materials of every description. In no other field of metallurgy are the economical advantages of transport by electricity so conspicuous as in connection with the use of lifting magnets, which enable the operator to seize the iron material at any point desired, conveying it to any other point within the range controlled by the crane. Incidentally, it should be noted that the use of lifting magnets eliminates much of the risk of accidents formerly connected with manual transport and the use of hand operated cranes.

Cranes with lifting magnets are of course used on a large scale also in connection with the loading and unloading of railway wagons with all sorts of iron material.

His Mattress a Life Raft

A RETIRED lieutenant of the U. S. Revenue Cutter Service recently hit upon the idea of making a life raft which may serve also as a mattress for use in bunks and beds on shipboard, as well as in houses and hotels along waterways where floods and overflows may take place suddenly and endanger the lives of the occupants. The mattress is constructed of resilient material provided with the usual ticking and surrounded with a waterproof and substantially airtight casing. This is further provided with an outer waterproof envelope to act as a protecting sheath for the inner casing. In place of felt the inventor prefers to use a resilient filler which is in itself a water-resisting material, so as to prevent the mattress from becoming watersoaked, in case the cover becomes ruptured or torn. In order to prevent the mattress from sagging in the center or bending under the great tortional stresses to which it may be subjected by the waves, a rigid marginal stiffening frame is provided. Lashings are also attached to each corner of the mattress, so that when it is used as a life raft they may be tied diagonally across the mattress to strengthen the frame and also to provide means for securing persons or articles to the float. In addition to this, loops and handholds are provided along the margin of the mattress. One of our photographs shows the mattress in use as a raft. In order to fairly test its efficiency, a mattress only 24 inches wide and of a size to fit the army transport stateroom bunk was punctured with seventeen holes and then heavily loaded with lead and floated in the water. It remained in the water for thirteen days, without showing any tendency to sink. The accompanying photograph shows the appearance of the mattress after this treatment.

The Edison Electric Safety Lamp

ON the evening of January 23rd, at the American Museum of Safety, New York, the Rathenau Medal granted by the Allgemeine Electricitaets Gesellschaft, Berlin, for the best device or process in the electrical industry for safeguarding industrial life and health will be awarded to Thomas A. Edison, for his safety miner's lamp. The desirability of using electric lamps in place of oil lamps, even those protected with a "Davy" wire screen, is strongly felt in these days. What is needed in mines is a positive light which does not depend upon the uncertain quantity of oxygen contained in the surrounding atmosphere, but is absolutely self-contained. Further, even a Davy lamp is not perfectly safe if through careless handling it is broken.

Mr. Edison's miner's lamp is operated from a storage battery of large capacity and very light weight, which may readily be carried upon the back of the miner in the manner indicated in the accompanying engraving. The nickel oxide battery is particularly adapted for such work where it is liable to be roughly handled, and subjected to such treatment as would put the ordinary lead storage battery out of commission in a short time. The battery is completely sealed and locked so that the miner cannot tamper with it, and it has only one miniature outlet for the escape of harmless gases when it is being charged. There is no danger of escape of the electrolyte even if the cell is inverted, because the outlet for the gas is at one end of the steel tube which extends downward from the top of the container to within a half inch of the top of the electrolyte, and is so formed as to preclude the escape of the solution even when the cell is violently shaken. The gases that pass off do not carry with them any substance to corrode the steel parts used in the construction of the lamp or the case of the battery or the clothing of the miner. No injury is done if the cell is overcharged and no harm comes to the plates if left semi-charged or discharged for an indefinite period. The cell may even be charged backward without serious consequences, although of course the battery will give no service unless charged in the proper direction. The only attention required aside from charging the battery is to replenish it with distilled water from time to time and renew the electrolyte after about nine or ten months of continuous daily service.

The flexible cord connector between the battery and the lamp is provided with a terminal which when shoved into the socket of the battery case becomes locked therein and cannot be removed until the padlock on the side of the case has been removed and the lock bar withdrawn. And so it is impossible for the miner to cause a spark by disconnecting his wires in the mine. To protect the conductor it is incased in flexible steel armor so as to prevent a sharp bend. A tungsten lamp is used with a parabolic reflector and a heavy lens to distribute the light over the proper area, and the lamp is provided with a hook that may be fitted to the regulation miner's cap. This lamp is the result of several years of persistent work on the part of Thomas A. Edison.

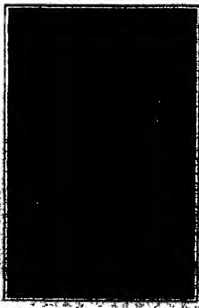
Using the mattress as a life raft.



Mattress after floating for 13 days.

The Life of London

FROM the London County Council's statistical abstract for 1911-12 some conception may be formed of the activities of that portion of Greater London which is confined to the county of London. It should be understood that Greater London, with an approximate population of 7,250,000, overlaps the county of London and passes into the counties of Middlesex, Herts, Essex, Kent and Surrey. Some of the figures given in the London County Council's abstract appear below.

Population, 4,522,961, debt, $558,858,960, weddings a year, 40,201, births, 112,795, deaths, 61,909, deaths by accident, 1,846, fires, 3,208, paupers, 140,560, police, 17,293, soldiers, 10,058, postal employees, 49,960; firemen, 1,365, motor cars, 8,318, postoffices, 1,061, letters delivered, 805,900,000; post-cards, 199,800,000, telegrams, 25,662,000.

The imports into London constitute 33.8 per cent of the total imports into the United Kingdom, and more than half the income tax on salaries is paid by London.

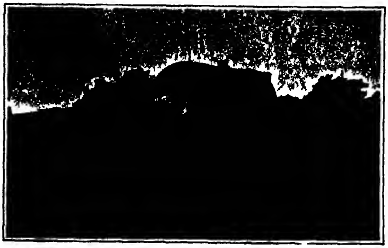
Motor Street Sprinklers in Europe

REGARDING the use of special power wagon outfits for municipal service, we may mention that the city of Paris is now employing a number of automobile sprinklers and sweepers, these being made by several different firms. It is stated that the city of Berlin is to purchase 16 combined sprinklers and sweepers, representing the sum of $40,000. As to the fire department work, the Berlin department now has 60 [illegible] in service, and [illegible] like those of Paris [illegible] are [illegible] by storage batteries. The [illegible] [illegible] [illegible] [illegible] is following [illegible] [illegible] [illegible] [illegible] [illegible] first of these [illegible] [illegible] and [illegible] will [illegible] made.

READERS are invited to contribute to this department photographs of novel and curious objects, unique occurrences, and ingenious contrivances. Such as are available will be paid for promptly.

Motor-pumped Street Sprinkler

IN order to provide a wider distribution of water from a street sprinkler a machine has been built which is propelled by a gasoline engine, and which has a double-acting water pump driven by the motor. With this combination the water may be spread over streets 70 to 80 feet wide on a single run. The operation of the pump may be governed to control the area to be sprinkled and to insure a uniform distribution of water. One of the objections to the usual type of horse-drawn sprinklers is the fact that the nozzles are placed at the rear of the vehicle, and do not prevent the raising of dust by the wheels and horses. In order that the motor truck may not cause the very evil it is designed to cure the spray nozzles are placed about a foot in advance and on either side of the motor hood. Thus the street is wet down in advance of the wheels and no dust is raised. The sprinkler shown in the engraving has a tank 4½ feet in diameter with a capacity of 1,400 gallons, which is mounted in a cradle and guyed with cross braces upon a 6½ ton chassis. A curious phenomenon may be seen in the illustration. The pulsation of the double action pump may be clearly observed in the spray of water thrown off from the nozzles.



Note the spurting spray caused by the pulsations of the pump

A Granite Statue of Electricity

THE Union Station at Washington is ornamented by six large statues ranging at intervals above the main entrance and looking out over the plaza that looks off to the Capitol building only a short distance. One of the statues representing Electricity is shown. It is the work of St. Gaudens and presents a majestic figure carved from a solid block of granite. The statues are probably the largest ever cut in a solid piece from granite and while they appeared colossal when on the ground as will be appreciated from the comparison with the two men standing alongside in the picture, they are well proportioned to the building when elevated to the high position they now occupy. The hoisting of the statues to a considerable height was no mean engineering proposition and was accomplished by suitable derricks and hoisting cables. To facilitate the operation the statues were supplied with a composite corset of heavy timbers and steel wire to receive the hoisting cables without injuring the carvings of the beautiful figures.

Raising the statue of "Electricity" at the Union Station, Washington

Legs of Max Unger's gigantic Frithjof monument

New Sanitary Drinking Fountain

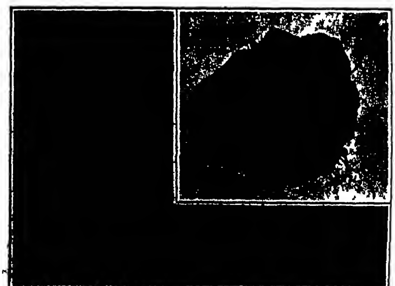
A NEW type of sanitary drinking fountain has been erected in Lafayette Square, Washington, D. C. This square lies immediately north of the Executive Mansion and almost in the shadow of the Cosmos Club of Scientists and the staid aristocratic St. John's Church which most visitors to Washington remember. The design of the fountain is rather ornamental, but unobtrusive. The fountain has a large basin into which the overflow from the nozzle cups discharges. The nozzle cups are at the outer ends of flexible tubes whose inner ends connect with the water supply, and the water flows up freely through an opening in the center of a dome-like plate rising almost to the top of the cup, so the user can drink without touching the metallic parts of the cup, out of which the water constantly flows in a [illegible] stream. The cups are shackled by individual chains to an upper portion of the foundation, so they cannot fall outside the basin when released by the drinker. [illegible] the cups when not in use discharge into the basin [illegible] the [illegible].

The "nozzle cup" fountain.

"Magnet Bill" saving automobile tires.

The Curious Lung Fish

A [illegible] has been [illegible] at the Museum of Natural History, New York that has shattered all popular conceptions of what a fish ought to be, as it possesses the surprising power of living six months, or possibly a year, out of water. Instead of a miniature aquarium or some sort of a box filled with the customary amount of water for its long sea voyage of thousands of miles the lung fish was transported in a block of dry earth which had only a funnel-like opening to admit air for the fish's breathing. This pit led into a tube of hardened slime which went into the fish's mouth and conducted the air directly into the lung of the fish. The lung fish, as it is called, breathes by means of gills when in water but with a lung during the summer drought, inhaling and exhaling air as though it were a land living animal. The fish came from the Gambian region of Africa coiled up in a kind of cocoon or capsule deeply sunken in a large clod of earth. To liberate the fish it was necessary to cut the hard earth away carefully from the papery cocoon. Then the cocoon was placed in tepid water to soften the shell which was formed by a mucous secretion on the surface of the fish's body. Within a few minutes the cocoon showed movements and shortly the fish emerged from it. The lung fish has been placed on exhibition in an aquarium in the Hall of Fossil Fishes. Prof. Bashford Dean states that it had been placed there because it is at home scientifically speaking among fishes which lived millions of years ago and whose race is almost extinct. A more complete description of this curious creature may be found in the current SUPPLEMENT.



African "lung fish" and a lump of mud containing the capsule in which it lives, breathing air during a drought.

A Gigantic Monument

THE German Emperor's passion for monuments expressed in a series of rather inartistic statues which have been mounted in the Siegesallee of Berlin to the intense amusement and disgust of all the comic weeklies in Germany is responsible for Max Unger's Frithjof monument. Next summer this colossal piece of work the mere legs of which are presented in the annexed illustration from *Moderne Kunst* will be unveiled in Norway to commemorate the twenty-fifth visit of the Emperor to that favored Scandinavian country. Naturally the monument is a gift from the Emperor and he himself will attend to the unveiling. The imposing legs herewith reproduced attain the majestic height of 23 feet. It goes almost without saying that the monument had to be made in small pieces. The statue will be erected on a peninsula opposite Balholm where according to tradition the graves of Ingeborg and Frithjof are to be found.

Saving Tires With a Magnet

HE doesn't look like a very important part of a big automobile factory organization, this tall, broad-shouldered, stooped and somewhat grizzled man who may be seen rain or shine, summer or winter, walking slowly about the plant, eyes almost constantly cast earthward, but he is an important item in the modern method of factory operation. Though his wage is that of the average workman, "Magnet Bill," as the grizzled man is known, is worth a good deal to the company by which he is employed. Bill gets his nickname from the fact that his tools consist solely of one tin bucket of the 10 or 12-quart variety and a big steel magnet strapped to the end of a short handle to allow for ease in operation. And his work is very important even though it looks simple to the passer-by, for it is Bill's duty to save automobile tires by removing from the roadway every nail and bit of iron or piece of steel that might cause a puncture. When it is known that 40,000 cars are run over this course to and from the places where they are tested, and scores of visitors' cars, office machines and delivery trucks use the thoroughfare daily, the value of Magnet Bill is at once apparent.

The Mercy of Steel and the Menace of Wood

A Study of Some Recent Railroad Accidents

WHEN the "Titanic" brushed elbows with an iceberg and tore open two hundred feet of her length, the public wondered at the frightful character of the injury. But the engineer did not wonder—he knew perfectly well, although he had temporarily forgotten it, that the one million foot-tons of energy in that onrushing ship was sufficient, had the obstruction been solid rock instead of crumbling ice, to have opened up the whole length of the ship, if the pressure of her helm had sufficed to hold her a little longer against the side of the iceberg. In multiplying length and breadth, tonnage and speed, naval architects had overlooked the fact that it was incumbent upon them to introduce under-water constructions which would limit the damage due to the enormous energy of the giant vessels of the twentieth century.

What is true of the sea is true also on the land. There has been an astonishing growth in the length, size and weight of the modern railroad train. Cars have tripled and engines have doubled in weight during the past three or four decades. Speed, also, has gone up to a higher figure, and with all this there has come an enormous increase in the energy, the destructive energy, of the train when it is developed by collision, derailment or other form of accident. Let us prove this by figures. The modern steel car weighs 70 tons and the modern express locomotive 200 tons. Such a locomotive on level tracks can haul ten such cars at a speed of seventy miles an hour, and on a down grade 80 miles an hour or more. At 70 miles an hour a train weighing 900 tons would have a striking energy of 150,000 foot-tons. If through disobedience or failure to see signals it dashed at full speed into a stalled train, it would strike a blow equal to that delivered by three of our latest 12-inch naval guns—and each of these, be it remembered, can bore a 12-inch hole clear through some 42 inches of iron.

How many engineers of fast expresses realize that if they were riding three 12-inch shells delivered at point-blank range, they would hit the target no harder than the fast-flying train which they hold in their hands would hit a standing train ahead.

Now when from 50,000 to 150,000 foot-tons of energy is suddenly arrested, whether by the instantaneous shock of collision or by the more gradual and multiplied shocks of a derailment, something has got to go; and just how it goes is shown by the accompanying series of photographic views of more or less notable railroad accidents which have occurred during the past eighteen months. They represent photographs of wrecks which were investigated by Mr. H. W. Belknap, Chief Inspector of Safety Appliances for the Interstate Commerce Commission. Federal inspection of railroad wrecks is a development of the past few years, and one has only to read the many careful and intelligent reports which are regularly issued by the Commission to understand that this section of their work is one of the most powerful of the many influences which are now working for the promotion of safe railroading.

The writer has selected these views with a view to emphasizing two truths: First, the peril of the faulty steel rail; and second, the merciful protection to life and limb which is afforded by the steel car. The first photograph shows the results of a derailment caused by a broken rail which occurred August 25th, 1911, on the Lehigh Valley Railroad near Manchester, N. Y., and resulted in the death of twenty-nine persons and the injury of sixty-two others. The track was first class and well maintained, consisting of 90-pound rails, with tie plates on each tie, the rails being double spiked on the inside of the rail through the plates. The train consisted of two engines and fourteen cars. The rail broke, probably under the engine, at a point 247 feet west of a steel girder bridge over Canandaigua Outlet. Two cars fell over the bridge. The first dropped endwise, and in it the majority of the fatalities occurred. The second car fell and stood on end as shown. The pieces of the broken rail were sent to the Bureau of Standards, Washington, and most carefully examined. It was found that the rail was what was known as a "piped" rail, and the report states that the piping or seam split could be seen in practically every portion of it. The illustration in the corner of our engraving shows this pipe represented by the fine black line extending through the vertical web. No inspection of the track could possibly detect a defect so completely concealed.

This accident, then, is chargeable to faulty work at the rail mills.

There is probably no defective member of which the railroad man stands in greater fear than the "piped" rail. It has been the cause of countless wrecks, some of them of the most disastrous character. The "pipe" is generally a hollow shrinkage cavity formed when the ingot is cast, which is closed up when the rail is rolled, and exists as an incipient flaw or fracture in the body of the rail, where it is generally entirely hidden from sight. Under the stress of traffic, cracks develop, spread and ultimately result in complete fracture. Illustrations VI and VII show broken sections of a rail which went to pieces under a train on the Great Northern Railway near Sharon, N. D., causing the death of five people and injuring eighteen others. The entire train of eight cars was derailed. The head of the rail was found to be split for a length of nearly eight feet, but the investigation showed that the initial rupture at the time of derailment was a crescent-shaped fracture in the base of the rail (shown in illustration No. VII) due to inclusions in the metal. The split head was due to segregation of the phosphorus and sulphur in the rail and irregularity in the carbon contents. These defects are chargeable to the present unsatisfactory methods of rail manufacture. They are curable by the use of such methods of ingot casting as that shown in our issue of December 21st, 1912, describing the Hadfield method of casting ingots.

The 90- and 100-pound steel rail, if properly made, will stand up to its work even under the exacting conditions of present heavy and fast traffic, provided it is thoroughly fastened to the ties, and ties and roadbeds are maintained in absolutely first-class condition. Illustrations III and IV show the derailment at Hyde Park, New York, March 31st, 1912, of the Twentieth Century Limited, while it was running on a 2-degree curve at a speed of 50 to 60 miles an hour. Says the Interstate Commerce Commission Report: "It is believed that the use of shims (small blocks of wood used to raise the tracks and placed between rails and ties), together with irregularities or unevenness in the track, so weakened the track structure that it could not withstand the strain due to the heavy locomotive and trains rounding the curve at high speed, and the outside rails were forced outward, probably by the engine."

From the point of derailment the outside rail of the curve was turned completely over for a distance of about 1,700 feet. The first rail to be disturbed is marked 1 in illustration II. On the inside of this rail eleven spikes were partially drawn, and on the inside of rail 1 the outside ties had been crowded outward more than their width. The engine, tender, a buffet car and one sleeping car remained on the roadbed. The remaining five cars, four of them of steel, rolled down the embankment and came to rest on the heavy ice of the Hudson River. This served to show first the insufficiency of the common form of track fastening to hold the outside rail on curves up to its place against the centrifugal thrust of the modern heavy high-speed train. The remedy is to be found in using tie plates beneath the rail on every tie and substituting the powerful screw spike for the archaic and very inefficient wedge spike, which, after all is said and done, is nothing more or less than a nonsplitted nail. The other lesson taught is the wonderful protection afforded by the strong steel car, which, even under such rough handling as this, was neither telescoped nor crushed. The picture of these cars lying intact on their sides, on the ice of the Hudson River, speaks for itself.

Further proof of the remarkable strength and stiffness of the steel car was given in the wreck last November of a fast passenger train on the Pennsylvania Railroad at Glen Loch, Pa. This was a heavy fourteen-car train of steel construction hauled by two engines. A box girder on a bridge which the train was crossing yielded under the weight of the two engines, the depression being about 18 inches, and the jar derailed the train. Five of the 75-ton steel sleeping cars were thrown down the embankment, the cars shutting up concertina fashion and coming to rest in the positions shown in the illustration No. IX, published by courtesy of the *Railway Age Gazette*.

Years ago, when the SCIENTIFIC AMERICAN was advocating steel-car construction, we pointed out that instead of the telescoping which was so frequent and so destructive of life with wooden car construction, the train of steel cars would probably yield at the couplings, the energy of the train being absorbed in folding up, as it were, the train. Now this is exactly what happened at the Glen Loch derailment. The only steel car seriously damaged of those shown in this picture is the one at the right hand, which turned over on its side, its roof colliding with a loaded coal car, and the relatively frail roof structure inevitably crumpling up under the force of the impact. Four people only were killed. Forty-nine were injured by being thrown around the cars.

The fragility of the wooden car and the fact that the work of developing the energy of the train will occur at its weakest point is shown in the illustrations V and VIII of a wreck on one of the southern railroads. The derailment was due to poor track conditions. The energy of the after part of the train, which remained on the track, completely telescoped two rather flimsy tourist wooden cars into less than the space formerly occupied by one of them. By far the most significant

(Concluded on page 102.)

I. A broken rail, due to pipe (corner cut) caused this wreck. Loss 29 killed, 62 injured.

II. View showing where an express [illegible] spread the track. Damage begins at rail 1, where eleven [illegible] were pulled.

III. Wreck due to spreading shown in adjoining cut. Note excellent condition of the steel cars.

IV. This train running at 60 miles an hour was derailed at a bridge. Note ex[illegible] condition of the steel cars. Roof of first steel sleeper smashed by coal car.

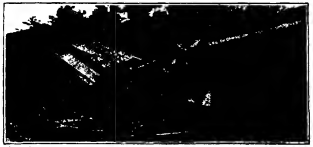


Photo. by Henry

V. The two weakest cars (wooden) in this train were telescoped into the space occupied by one car.

VI. Split head [illegible] to pipe.

VII. Base fracture where [illegible] began. The rail shown in VI and VII [illegible] loss of five lives.

VIII. General view of derailment which telescoped the wooden cars shown in opposite illustration.

These three illustrations show the relative behavior of steel and [illegible] cars in the disastrous rear-end collision at Corning, New York.

IX. Between engine and steel car is wreckage of wooden car.

X. Steel car after crushing wooden [illegible] and two thirds of wooden sleeper.

XI. Steel car and wrecked two thirds of sleeper.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel

REVERSIBLE VEST.—W. FREEMAN, 840 Jefferson Av., Brooklyn, N. Y. The invention relates to a form of reversible vest and more particularly to that class wherein the different faces present vests of different character. It is adapted to be worn to present in effect either a single or double breasted vest and a vastly different appearance along the fast ening line is eliminated and a smooth tailored effect is produced.

SHOE HEEL.—H. ROSENBERG, 968 Kent Av., Brooklyn, N. Y. This invention provides a cushion section for a shoe heel and a wearing surface therefor rigidly secured thereto, provides a heel with a felt section leather covered to harmonize the appearance of the section with the shoe upper and the wear ing lifts, and provides means for uniting the felt section and the body of the shoe.

POCKET BOOK AND POWDER PUFF.—A. WINDLER, 1037 3rd Av., Manhattan, N. Y., N. Y. The invention is an improvement in pocket books and supplies an article having a false bottom . . . . bottom . . . . be . . . . puff to be used.

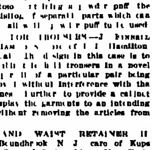
CABINET FOR TROUSERS.—J. FINNERTY and J. I. HAMILTON, care of J. I. Hamilton, Red Bluff, Cal. The design in this case is to provide a cabinet to hold trousers in a novel manner to . . . . of a particular pair being readily . . . . . . without interference with the remaining ones. Further to provide a cabinet that will display the garments to an intending purchaser without removing the articles from the cabinet.

SKIRT AND WAIST RETAINER.—H. GITIGS, R. Brandbrook, N. J., care of Kups Bros., 16th St. and Irving Place, New York, N. Y. This retainer is adapted to be removably fastened to the front steel of a corset and an object is to provide a device which may be used to hold a skirt in position and to afford means for holding the shirtwaist tap or band in place close to the band of the skirt to afford a neat smooth connection at the waist.

Pertaining to Aviation.

CONTROL FOR AEROPLANES.—W. A. BARTHOLOMEW, Ravenna, Mich. This improvement relates more particularly to a device for the transverse controlling of the planes and provides a structure which will act at or near the extremities of the planes or other convenient points for causing the aeroplane to maintain its proper equilibrium or return to its proper position quickly when moved therefrom.

FLYING MACHINE.—B. QUESADA, San Jose, Cal., care F. W. Dinaggi, 414 San Jose Bank Bldg., San Jose, Cal. This invention comprehends a number of distinct features relating to the wings, the prime mover and its connection with the propellers, a truncated conical body portion, and various other mechanical features for increasing the efficiency. The



FLYING MACHINE

essence of these improvements lies in the particular curvature given to different parts of the wings and the mechanism for conforming these curvatures and maintaining the same. The stability obtained by shaping the wings is almost positive and enables the machine as a whole even after power is shut off completely to descend almost as easily and as gracefully as a parachute. A side elevation of the machine is shown in the engraving.

Electrical Devices.

TELEPHONE INSTRUMENT.—M. M. RAY, S. . . . care of American Tel. Co., 66 Broadway, New York, N. Y. This inventor provides supporting means for the receiver to dispense with the need of holding the receiver in the hand, provides supporting means for the telephone receiver which will be moved to service position automatically; has the necessary circuit to the instrument provides a means where by when use of instrument is discontinued the circuit is automatically cut off, and provides means for at will locking the instrument in position to maintain open the line circuit during intervals of suspension of use.

TELEPHONE ATTACHMENT.—M. M. RAY, S. . . . care of American Tel. Co., 66 Broadway, New York, N. Y. This invention relates to an attachment whereby the user will not be put to the inconvenience of holding the receiver while talking and whereby he may have both hands free to take notes of the telephone conversation if necessary.

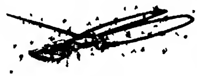
ELECTRICAL MELTING AND SOLDERING APPARATUS.—W. M. BOWLES and C. O. ALLAN, 117 N. Philadelphia St., Shawnee, Okla. An object of this improvement is to provide a heating device for use in melting or soldering metals with great facility and with a minimum expenditure of heat. A further purpose is to provide a portable device which can be readily connected to an electric circuit.

RHEOSTAT.—W. M. BOWLES and C. O. ALLAN, 117 N. Philadelphia St., Shawnee, Okla. An object here is to provide a variable resistance for controlling an electric current in which the resistance members consist of a series of carbon disks. A further object of the invention is to provide means for varying the contact between these disks and thereby throwing into the circuit more or less resistance.

Of Interest to Farmers.

FARM GATE.—A. M. DOYLE, Leoti, Kan. This invention has reference to operating devices for gates such as are used specially in rural places and where it is desirable to avoid the inconvenience and frequent danger to a person traveling alone from dismounting from his horse or vehicle to open the gate.

CATTLE STAKING DEVICE.—R. J. LEE, care of Blue Ridge Hosiery Mill, Landrum, S. C. This invention has reference more particularly to a device comprising a manipulating member, a chain or other flexible element secured at one end to the manipulating member and serving for the fastening or staking out of an animal and means associated with the manipulating member whereby the flexible member can be taken up and shortened. Be

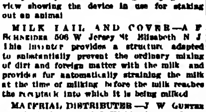


CATTLE STAKING DEVICE

sides for use in staking cattle or other animals for grazing it can be employed in driving cattle or in fastening or tying them under different conditions with means for carrying the chain or other flexible tying member so that the latter cannot become entangled or endanger the animal or the driver. The flexible member can be lengthened or shortened within the limits of its length which can be very easily manipulated. The engraving gives a view showing the device in use for staking out an animal.

MILK PAIL AND COVER.—A. F. SCHNEIDER, 506 W. Jersey St., Elizabeth, N. J. This inventor provides a structure adapted to substantially prevent the ordinary mixing of dirt and foreign matter with the milk and provides for automatically straining the milk at the time of milking before the milk reaches the receptacle into which it is being milked.

MATERIAL DISTRIBUTER.—J. W. GUNTER and J. A. HAMBY, 112 Highland Ave., Montgomery, Ala. The invention has for its object the provision of an inexpensive machine wherein means is provided for insuring a regular and uniform feed of the material operated directly by the movement of the machine and



MATERIAL DISTRIBUTER.

wherein the feed may be regulated to suit conditions. In operation a cut off is set to feed the requisite amount of fertilizer and is held in this position. The machine is drawn over the ground the wheel in front rotating the shaft and causing the fertilizer to be fed through the chute. The plow opens a furrow to receive the fertilizer and a plate covers the fertilizer in the furrow. The accompanying illustration shows a side view of the distributer.

DRILL SHOE.—F. KRAUSE, care of Tobias D. Casey, Dickinson, N. D. The purpose here is to provide a shoe having an elongated body with its rear flared at the bottom and a seed spout secured to the body with its bottom bent for directing the seed under the flared portion of the shoe. The seed spout is open at its rear end and closed at its front end to prevent its being clogged with dirt.

WEED CUTTER.—J. F. BORCHERS, Cashmere, Wash. This implement clears the ground of weeds of the type which is designed to be pulled by a draft animal when in operation, and it comprises a frame carrying means for cutting weeds and other objectionable vegetable growths and supported upon a plurality of adjustable guides which enable the frame to move over the ground at any height therefrom.

PEANUT THRESHING DEVICE.—C. R. LIVERMON, Roxobel, N. C. An object in this invention is the provision of a means for separating the peanuts from the vines and for delivering the peanuts cleared from chaff and dirt from one part of the machine and for discharging the vines from another part of the device.

Of General Interest.

FIRE ESCAPE.—M. FINK, 15 W. 118th St., Manhattan, N. Y., N. Y. This escape permits a person to safely lower another or a number of persons successively from a burning building to the ground, and allows persons to lower themselves, and without danger of injury by falling or by striking the ground

FIRE ESCAPE.

on being lowered or in case the person should lose his grip. Use is made of a rope for attachment at the upper end to a fixed holder located at or adjacent to a window or other opening and a supporting harness permanently secured to the lower end of the rope and adapted to be attached to the person intending to escape. The illustration shows a perspective view of the fire escape as applied.

CARD CASE ATTACHMENT FOR PENCILS.—A. B. SCOTT, Fairmount, W. Va. This invention more especially relates to pencil attachments for holding an identification card or the like and objects of the improvement are to provide an attachment that may be applied to an ordinary pencil and hold the

CARD CASE ATTACHMENT FOR PENCILS

card rolled into small compass and concealed entirely within the case to provide for the control and manipulation of the pencil to project and withdraw the lead by operations independently of the case and holder and to provide holder of neat and compact construction. The engraving shows the body of the card case removed and the end member or cap of the case in section the card being shown unrolled.

BUMPER.—F. PHILIPPIN, care of Brevoort House, 5th Ave. and 8th St., New York, N. Y. This invention refers generally to bumpers, and more particularly to an article especially adapted for use on the bow of a vessel or boat, whereby the liability of damage to a vessel or boat in the event of collision is mate-

BUMPER.

rially reduced. The bumper is of a resilient construction and is provided with means whereby it may be efficiently held in position on the ship. A perspective view is shown in the engraving of the bumper in position at the bow of a vessel.

SAMPLE CARD.—B. F. . . . . plex Litho. Co., 444 1st Ave., Manhattan, N. Y., N. Y. It is customary in . . . . fabrics to cut up material into pieces and card or "mount" them, and this entails large expense, not only for sample materials, but for the labor of cutting and . . . . material to the cards, and it is . . . .

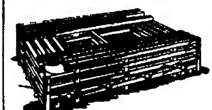
. . . . display . . . . without the necessity of . . . . samples actually cut from goods that . . . .

CONTRACTIBLE UMBRELLA.—A. M. . . . . 1444 Park . . . . ., Wichita, Kan. In this umbrella the canopy together with the staff, is adapted to be shortened and inserted in the handle as when the umbrella is not in use. For this purpose the handle is expansible so as to open out when the canopy and staff are passed within it, and assume a conventional size when used as ordinary.

SUPPORT FOR CONCRETE REINFORCEMENTS.—C. A. KOSMAN, 511 Walker Bldg., 5th and Market Sts., Louisville, Ky. This invention has reference to supports for the steel or other reinforcements for concrete, and has for its purpose the provision of a structure which will correctly support the reinforcing members without defacing the finished work.

ACETYLENE-OXYGEN WELDING TORCH.—J. D. FRIAR, care of Fred. H. Buchanan, Centerville, Kan. This inventor provides a simple and inexpensive device for receiving and mixing the gases, wherein means is provided for thoroughly mixing the said gases as they pass to the outlet and without delaying their passage.

LIFE RAFT.—B. N. MATSON, Boston, Mass. This raft is intended to be carried by marine vessels, and the device is formed of a plurality of buoyant members, and airtight and food tanks crated in the buoyant members, all forming the raft. The raft with parts of the



LIFE RAFT

frame or crate cut away and showing the food tank is pictured in the accompanying engraving. It is safe simple and rigid in construction and equally efficient when being launched either side up. The buoyant members inclose a plurality of air and food compartments evenly spaced and crated by the buoyant members, and guaranteed from injury by the said members.

COMBINED CIGARETTE BOX AND MATCH HOLDER.—H. A. GRIFFIN, Drawer R, Rocky Mount, N. C. The match holder and igniter is pasted on the front of the cigarette box proper and is so constructed as to normally cover and protect the fulminate ends of the matches but serves to ignite a match when being withdrawn.

ICE MAKING APPARATUS.—S. R. BELL, 498 Walnut St., Beaumont, Tex. The intention here is to provide an apparatus having combined means for making the ice and for cooling the brine which is used in the ice making process thereby dispensing with additional apparatus for cooling the brine.

LIFE BOAT.—P. E. BÜROW, 1118 8th Ave., Brooklyn, N. Y. An object here is to provide an open top power boat which cannot fill by the breaking of the seas over the same and which is so constructed as to obtain the maximum bearing surface upon the water and which has its center of gravity relatively low.

DEVICE FOR HOLDING AND DISPENSING BEVERAGES.—J. VERNANO, care of B. D. BERNADI, Santa Rosa, Cal. The aim of this inventor is to provide a barrel, tank or other receptacle or container, with a plurality of separate compartments adapted to contain liquids of different characteristics together with a single dispensing faucet having com-

DEVICE FOR HOLDING AND DISPENSING BEVERAGES.

munication with each of said receptacles or container compartments, and so constructed that a liquid . . . . compartments may be . . . . mixture with the . . . . ing this invention.

PORTABLE . . . .—F. L. Mayne, care of . . . . Ave., ..., Pa. This . . . .

of the harness; and provides a frame having means incorporated therein for adjustment to suit service conditions of the trough when used by horses of various builds.

VAPORIZER.—G. A. Evans, 909 Bedford Ave., Brooklyn, N. Y. This vaporizer is used for giving off, or in a certain sense exhaling particles of medicinal substances through air passed thereover so that the medicinally charged air may be used for the treatment of diseases of the lungs and the air passages.

COMBINED CUFF BUTTON AND CUTTER.—L. Kalisa, care of Midget Mfg. Co., 175 Center St., New York, N. Y. The intention in this case is to provide a new and improved combined cuff button and cutter designed to be worn as a cuff button and adapted to be used as a cutter for use in cutting finger nails, cigars and the like.

FOUNDATION.—R. Frankignoul, 196 Rue Gretry, Liege, Belgium. This invention relates to the making of foundations of buildings and structures in a manner to enable the verticality or horizontality of the buildings to be quickly and easily restored, should they be interfered with by movements of the ground due, for example, to mining operations.

PROCESS FOR TREATING RAW POTATOES IN ORDER TO OBTAIN BOTH A CATTLE FOOD AND A PROTEID.—H. Gumpel, Schlagenthin, near Damsdorf Müncheberg, Germany. The process is effected by separating the juices from the potatoes after they have undergone a suitable preliminary treatment and to use these juices for the manufacture of the proteid substances, while the solid residue is used for the manufacture of the durable animal food.

BOOT CLEANER.—A. M. Fairfield, St. Marys, Kan. The cleaning devices are placed on the floor, and conveniently supported to permit the user to place his foot against the scraper and brushing members. The object is to provide a cleaner, to the end that the shoe may be quickly and efficiently cleaned by the brushing elements of the cleaner.

MUSIC HOLDER.—E. J. Barrett, Onaway, Mich. This invention relates more particularly to holders adapted for use on pianos and like instruments, and provides a construction light in weight, readily portable, which may be quickly and easily set up in operative engagement with the piano or other instrument and detached therefrom.

CARD INDEX.—L. C. Reynolds, 712 Quincey St. N. W., Washington, D. C. This improvement is in indexes in which a series of cards having names or matter printed thereon, in alphabetical order, are held detachably in a frame one above another, so that the matter is always visible on the faces of the cards, each of which is provided with some form of device adapted to engage and support the one above it.

FLUID ACTUATED GONG.—G. R. W. Rommers, 2346 San Antonio Ave., Alameda, Cal. This invention relates to gongs for street railway cars, or any other vehicle which has an air brake system or is capable of carrying fluid under pressure. It provides means whereby to continuously sound a gong without effort on the part of the operator subsequent to the opening of a valve for the purpose of starting the actuation.

FEED REGULATOR FOR GRAVITY CONCRETE MIXERS.—G. W. Mills and J. E. Simpson, Georgetown, Pa. The invention provides a device wherein the different materials forming the concrete are mixed in the proper quantities, during their passage by gravity through the device, and wherein means is provided for insuring the proper distribution of the materials before the mixing operations begins.

Hardware and Tools.

WRENCH.—C. G. Youngquist and C. F. Youngquist, 526 Henry Bldg., Portland, Ore. This invention provides a wrench with jaw members which are movable relatively to their supporting heads to assist in obtaining a firm hold on a pipe, resilient means being provided for holding the jaw members yieldingly in position relatively to the supporting heads.

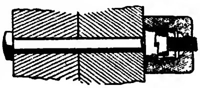
FAUCET CONNECTION.—P. F. Kistlow, care of Dr. E. M. DeCastro, 895 Union St., Brooklyn, N. Y. The invention pertains to connections for water spigots, particularly to those for connection with shower bath or bath spray apparatus. A hose connection or the like is made to spigots or reducers of various sizes, without the necessity of making any substitution or alteration in the connection.

SAW GAGE.—G. Ferris, Park Falls, Wis. The invention shown in a side view in the illustration is a structure which automatically indicates the bend or curvature of a saw applied thereto. The gage indicates on a scale the amount of curvature, the action of the

SAW GAGE.

[illegible] automatic upon placing the gage [illegible] the saw or other [illegible] having a centrally [illegible] held in an [illegible] mounted arm which moves over a graduated scale whereby when the support is placed upon a surface the motion is transmitted to the pointer for indicating the degree of curvature of the surface to which the gage has been applied.

NUT LOCK.—C. J. Ivers, Rushmore, Minn. This invention has for its object the provision of a nut which may be screwed upon a bolt, but which when once adjusted, is prevented from becoming unloosened, and which will, in fact, have to be cut off if it is ever removed. A further object is to provide a simple and inexpensive form of device for absolutely pre-



NUT LOCK.

venting the removal of the nut by unscrewing it when it is once in position. The device is designed for use on structures in which the permanent position of the nut is desired, and is shown in the accompanying illustration in a section through the nut after it has been applied.

FLUE EXPANDER.—J. B. Anderson, Clipper, Wash. In this case the invention has reference to improvements in flue expanders, and it has for an object the provision of an improved structure in which a screw construction is provided for feeding the device forward during the expanding of the tube.

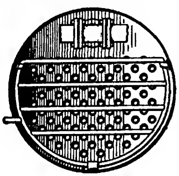
SCREW DRIVER.—G. B. Mullen, 18th St. and 7th St., Whitestone, New York, N. Y. This invention relates to screw drivers for inserting and withdrawing wood or other screws, and has reference more particularly to one having a shank, a blade at the end thereof and adapted for engagement with a screw head and a clamp associated with the driver and adapted to hold the screw in position relative to the blade.

KNIFE.—J. A. Hanson, 141 Riverside Drive, New York, N. Y. The object here is to provide a knife having a detachable blade which is held against the handle by a hook rod, the hook on the rod engaging the blade around an orifice and the rod being secured in a channel in the handle. The blade is reinforced by a bar, the butt end of which is disposed in a socket handle.

Heating and Lighting.

FIREPLACE.—G. L. Perrins, Sanford House, Excelsior Springs, Mo. Mr. Perrins's invention is an improvement in that class of fireplaces in which the side walls converge to the rear and a horizontal ledge or step extends between such walls. Practical use of the invention has demonstrated that in this fireplace a maximum calorific effect is produced with a minimum of fuel.

SMOKE CONSUMER.—R. H. Sharp, 2334 Tower Grove Ave., St. Louis, Mo. The invention relates to smoke consumers and it has for its object to provide a flue boiler with pipes with openings at the front of the boiler through which air may be carried to mix with the heated gases coming from the flues at the front of the boiler to complete the combustion.



SMOKE CONSUMER.

Various applications of the invention may be used, since the invention includes all constructions in which air is admitted between the fire chamber and the smoke-stack, whether flue boilers are used and whether the boilers are stationary or of other types. The engraving represents a sectional view of the boiler, to which the smoke consumer is applied.

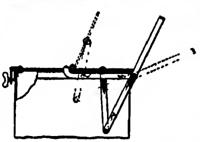
ACETYLENE GAS GENERATOR.—J. F. Williams, 41 Warren St., New York, N. Y. The object here is to indicate at all times the amount of carbid in the feed hopper and to sound an alarm whenever the carbid in the hopper reaches a low stage, and whereby a supplementary charge of carbid within the hopper may be added to permit of running the acetylene gas generator another length of time, say overnight, before being required to recharge.

CAST IRON BLAST HEATER.—K. Meier, 12 Fuchsbrunnen, Winterthur, Switzerland. This heater is arranged to provide a large heating capacity for the air in a comparatively small space, to permit increased velocity of the air and to minimize the resistance to the flow of air and reduce the power required for forcing or drawing the air through the steam, hot water or other heater and to avoid dead air spaces and thereby make the heater self cleaning.

BOILER.—W. Johnson, University Place, Neb. The invention has for its purpose the provision of a boiler suitable for providing steam for motors, or for heating systems, having a special form of heating means, arranged to give the largest possible amount of steam per heat unit.

HOT WATER HEATER AND STERILIZER.—C. J. Madonna, 443 7th Ave., Brooklyn, N. Y. The intention here is to provide a hot water heater and sterilizer more especially designed for use in barber shops, hospitals and other places and arranged to furnish a supply of hot water for shaving, and washing purposes, and at the same time permit the sterilizing of a large quantity of towels, napkins and the like.

ASH CAN COVER.—E. M. Coryell, 410 Richmond Ave., South Orange, N. J. This inventor provides a cover separable from the can which may be opened by laying the shovel with the ashes thereon on a projecting bracket the weight of which shovel and contents will automatically open the cover to permit the quick insertion of the ashes into the can, the withdrawal of said shovel automatically closing the cover. The cover is of two parts hinged together, one adapted to be removably



ASH CAN COVER.

fastened to the can and carrying a support projecting forwardly of the other part which support forms a fulcrum for the lever. One end of said lever is attached to said other part, and the opposite end of the lever projects forwardly of the can as a rest for the shovel. A side elevation of the invention attached to a can, parts being broken away to show the attachment, and the lid and its attached parts shown in raised position in dotted lines, is illustrated herewith.

Household Utilities.

FLUSHING DEVICE.—A. Williman, care of N. C. Abbott, 710 1st Nat'l Bank Bldg., Houston Heights, Texas. In the present patent the invention has reference to a flushing device that will operate to flush a closet, or other apparatus, without the use of a separate water tank and obviate the attendant disadvantages of a water tank.

BROOM HOLDER.—W. J. Horn, Tunica, Miss. Means is here provided for connecting a broom to a handle in such manner that a considerable degree of resiliency is permitted between the broom and the handle and wherein the clamping means may be adjusted for brooms of various sizes, and wherein the handle may take a position at an angle with respect to the body and wherein a positive gripping means is provided in connection with the clamping means.

WEATHER STRIP.—G. L. Godfrey, 1530 Bryant Ave., New York, N. Y. This invention provides a metallic strip to close an aperture irregular in form and varying in width, and provides a rigid metal casing, a movable stop member mounted therein, and means carried in said casing for compelling the sections of said stop member to conform with the contour of the opening to which the strip is applied.

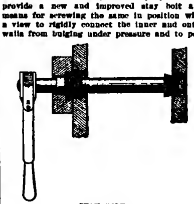
COMBINED MOP HOLDER AND WRINGER.—J. W. Kauboek, Darwin, Minn. This invention provides a mop having a construction adapting it for combination with a scrubbing device, improves the elements entering into the operation and supporting means of the mop head device, and provides a scrubbing device having means for holding a scrubbing brush adapted for co-operation with the novel mop heads and their appurtenances.

CHILD'S PORTABLE HIGH CHAIR.—F. Gassman, R. F. D. No. 3, Alva, Okla. This invention is an improvement in legless high chairs, in which the seat and back are hinged and adapted to fold together, and provided with a hook like attachments adapted for supporting the chair-proper on the back of an ordinary chair, or on hooks or other devices secured to a wall or other rigid support.

SINK FRAME BRACKET.—W. J. Daly, 314 N. Main St., Mason City, Iowa. The bracket is simple and inexpensive, and may be of any desired size and weight. The parts may be made in stock sizes and adjusted to a wide variety of dimensions. The sink is held firmly and without any possibility of accidental dislodgement, yet is easily removable for cleaning or repairs.

Machines and Mechanical Devices.

STAY BOLT AND MEANS FOR SCREWING THE SAME IN PLACE.—W. L. Decker, per Calicia No. 9 Mollendo, Peru. The invention relates to boilers, and its purpose is to provide a new and improved stay bolt and means for screwing the same in position with a view to rigidly connect the inner and outer walls from bulging under pressure and to per-

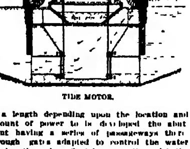


STAY BOLT

mit of conveniently and quickly screwing the stay bolt in place or removing the same when necessary. The engraving herewith shows a side elevation of the stay bolt partly in position on the inner and outer walls of the boiler, the boiler walls and guide nut being represented in section.

CONCRETE MOLD.—W. H. Alexander, Box 175, Long Branch, N. J. The object here is to provide a mold having a bottom member which may be conveniently raised and lowered so that a detachable end member will rest on the ground, the mold being provided with side members which have clamps for engaging the detachable end member and means by which the side members are moved laterally relatively to the bottom member.

TIDE MOTOR.—F. D. Taylor, 911 Pontiac Ave., Providence, R. I. This invention relates to hydraulic motors and particularly to power devices adapted to utilize the force of both the ebb and flow of the tide. The motor comprises a fixed abutment constructed at any convenient place such for instance as at the mouth of a bay, inlet, or river of a height preferably slightly below the water line at low tide and



TIDE MOTOR.

of a length depending upon the location and amount of power to be developed, the abutment having a series of passageways therethrough, gates adapted to control the water passing through, a float in connection with the abutment, shafts for operating the gates and means carried at a uniform elevation of the float for operating the gate controlling shafts during changes in the elevation of the float. The illustration shows a vertical transverse section of the invention.

ADJUSTABLE STOCK FOR FIREARMS.—O. E. Oliver, Mount Eden, Alameda Co., Cal. Mr. Oliver's invention is an improvement in that class of gunstocks in which the butt section or stock is pivoted to the front section or grip, so that the two may be adjusted at differ-

ADJUSTABLE STOCK FOR FIREARMS

ent angles to each other. By the construction and combination of the various parts a joint is formed distinguished by simplicity, lightness, strength and rigidity. The butt section is adjusted up or down to suit a long or short-necked gunner or sportsman or it can be adjusted sidewise to the right or left to suit a wide or narrow shouldered man or a right or left handed gunner as the case may be. The accompanying engraving shows a longitudinal vertical section through the pivoted adjustable stop.

FARE RECEPTACLE.—G. C. Stewart, 2604 W. Main St., Louisville, Ky. This improvement is in receptacles in which are deposited the fares of passengers of pay as you enter cars and other vehicles used for public transportation. All coins taken from passengers and deposited in the mouth of the receptacle must drop into the box before the base of the receptacle can be opened and the box removed; and, hence, the danger of loss to a

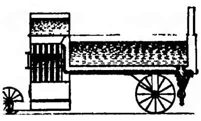
company through thieving is reduced to the lowest minimum

THREAD CUTTING ATTACHMENT FOR SEWING MACHINES.—Robert L. Colay, care of James W Cannon, Concord N C. The object in this case is to provide a simple attachment capable of attachment to any form of machine with but little change and for automatically cutting the thread between articles without stopping the machine and without injuring the article

VALVE GEAR.—E I Robertson, 220 Mulberry St., Greenville S C. The present invention has reference to valve gears in which the valve rod receives its motion from the usual link mechanism and return crank through the medium of a lap and lead lever having a link and hanger connection with the cross head of the piston rod

MOTOR STARTER.—A J Charlton, Lowden, Iowa. This improvement is in motor starters in which a spiral member co-acts with another one being rotatable so that by sliding or rectilinear adjustment of one of the members, the other one is rotated with the effect of imparting rotation to the motor shaft

MACHINE FOR HEATING AND DISTRIBUTING MATERIALS.—J F Decker, 7 Third Ave, Albany N Y. This invention has reference to machines for use in heating and distributing materials, and it has for its object to provide such a machine which may be used



MACHINE FOR HEATING AND DISTRIBUTING MATERIALS

to heat crude oils, asphalt etc and to distribute them on roads. The machine is provided with a water boiler and a tank for the materials which are heated, steam from the boiler being supplied in jets to the nozzles which distribute the material on the road. A longitudinal sectional elevation of the invention is represented in the illustration

MEANS FOR CASTING FINGER RINGS.—F H Curl, 2116 E 4th St, Longbeach, Cal. The invention relates to molding operations similar to the means set forth in a previous patent granted to Mr Curl. The primary object is to improve the means for casting finger rings or similar symmetrical articles, whereby the operation may be performed much more rapidly and cheaply and with less mechanism or fewer parts than was necessary in the previous operation

MACHINE FOR CAPPING AND DOUBLE SEAMING CANS.—H L Guenther, 278 N Ave 23, Los Angeles, Cal. This inventor provides a machine for capping and double seaming cans, arranged to restore the mouths of can bodies which have become distorted while being filled or handled to press the fruits or other food products, that may extend above the edge of the can body downward into the same to place the can heads in position in the can bodies and to double seam flanges of the can bodies and heads, and to compress the seams to render the same airtight without the use of solder and to remove the finished cans from the machine

WINDMILL.—W T Santala, P O Box 353 Georgetown, Conn. The object here is to provide a mill arranged to hold the windmill at all times in the wind and to permit of exposing more or less of the wheel to the action of the wind according to the power thereof thus insuring a proper running of the wind wheel in light or heavy wind

CLOSING DEVICE FOR DYEING VATS.—C P Delahunty, care of Delahunty Dyeing Machine Co, W Pittston, Pa. An object of the present invention is to provide a readily manipulated cover which may be actuated manually irrespective of its weight and is especially adapted for large sized tanks where some mechanical arrangement must be utilized in order to entirely uncover the vat so that the opening is entirely unobstructed when filling the vat

ABRASIVE BELT MACHINE.—C H Dunsy, care of John C Stephan, Midland Furniture Co, Evansville, Ind. This invention has reference to abrading or polishing machines and has particular reference to devices of this character adapted for a wider range of adjustment and field of operation than other machines previously proposed

DEVICE FOR EXHIBITING PICTURES.—A S Warren, 20 Prospect St, Batavia N Y. This device involves reels or spools for receiving a strip bearing pictures that may be brought into view successively and it is a design to provide a device wherein a plurality of supporting and guiding devices are so arranged that a strip bearing pictures on opposite faces thereof may be so moved as to exhibit the pictures on either side of the strip or film

DITCHING MACHINE.—A E Hanson, Mason City, Iowa. The object of the present invention is the provision of a new and improved ditching machine arranged to readily form the ditch to any desired depth, and to divide the material and deliver the same to opposite sides of the ditch in a very simple and economical manner

MACHINE FOR USE IN THE MANUFACTURE OF INCANDESCENT GAS MANTLES.—J I Robin, 54 Cheapside, London, England. This invention has reference to the manufacture of incandescent gas mantles, and while it is particularly applicable to mantles of the kind which are composed of loose strands or threads it may also be applied to the manufacture of any ordinary form of mantle

SWIVEL FOR HOISTING MACHINERY.—A C Graham, Oilfields, Cal. The invention provides a pivotal engagement for uniting the hoisting cables and the elevator links of a well casing and provides an engagement means for uniting the parts of a hoisting mechanism constructed and arranged to minimize the weight and economize the cost of construction

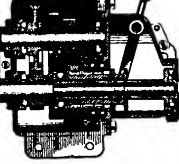
HYDRAULIC RAM CYLINDER.—O P Bushnell, care of Monarch Machinery Co, 30 Church St, New York, N Y. The principal object here is to provide a cylinder formed from cast steel and to avoid defects incident to the construction thereof. Other objects are sought such as forming a construction wherein the parts are stronger and lighter and to provide a structure wherein the method of manufacturing the same is simplified.

FLYING MACHINE.—W Phillips, Edison Park, Chicago, Ill. This is an improvement in flying machines of the helicopter type involving a vertically arranged car body within which the aviator is stationed and from which he has control of the machine by virtue of novel steering and balancing devices. The invention also includes among other details of importance a peculiar means for manipulating the legs upon which the device is supported when not in the air

REVOLVER.—R B Holmes, Ferndale South Bellingham, Wash. An object here is the arrangement of a structure having a high power confined to a minimum space. Still further is the arrangement of a revolver formed so as to be held in the palm of the hand so as to be substantially hid from casual observation and adapted to be quickly discharged upon the successive closing and opening of the hand

CHEESE MAKING MACHINE.—E Veaman, Jonre, Holland. By use of this machine the curd will be effectively broken up and thoroughly worked to a uniform and superior condition the mechanism having provision for effectively extracting the whey and effecting its discharge while collecting the curd in an annular layer in the containing vessel against the inside surface of the side wall of the vessel

CLUTCH.—J Chalmers, 82 River St., Quincy Mass. This invention relates more particularly to the clutch mechanism in transmission gearing in which the rotary motion is transmitted at different speeds through two sets of gears running on parallel axes of which gears some are loose on one of the shafts and



CLUTCH

are provided with a clutch device for connecting them at will so that the motion may be transmitted through any one of the gears desired and consequently at speeds proportionate to the ratio of these transmitting gears. The novel features reside especially in the peculiar construction and organization of the mechanisms for connecting the loose gears at will with the transmitting element co-acting therewith. The engraving shows a transverse sectional view taken longitudinally through the invention.

SCALE.—C M Sturgis, 1601 5th Ave., Birmingham Ala. This invention has particular relation to improvements in the construction and arrangement of parts composing a scale shown in a former patent granted to Mr Sturgis. The principal object which the present invention has in view is to simplify and economize the construction, and with this in view it consists in providing a main rocking bar and standards therefor having knife-edge alined supports for the bar.

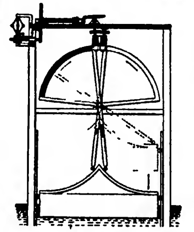
BARREL SOAKING AND RINSING MACHINE.—H Rainings, care of Consumers Brewing Co. New Orleans, La. This invention has for its purpose the provision of a new and improved apparatus which will quickly and continuously handle barrels, kegs or the like, for washing the same automatically after the same have been once fed into the machine.

PUMP OPERATING APPARATUS.—W Ellsworth, Smyrna, Wash. This invention is a means for converting rotary motion into reciprocating motion for the purpose of operating pumps and other machinery. It is especially useful for pumping water in irrigated districts, for emptying deep wells, or for supplying water from springs and streams.

Prime Movers and Their Accessories.

ROTARY VALVE FOR INTERNAL COMBUSTION ENGINES.—R O Witwer, New Hamburg, Ontario, Canada. The valve is arranged to control the admission of the explosive mixture and the exhaust for the products of combustion in a simple and effective manner to operate with uniform efficiency at all speeds, to reduce the water-cooled surface of the explosive chamber to a minimum, and to require but little power to actuate the valve

TIDE MOTOR.—W Braunsdorf, 3411 Broadway, New York N Y. The object here is to construct a tide motor which will utilize the buoyant force of the rising tide to lift a float, and which float during the flow of the tide will be operative through its weight to drive any suitable machinery in the same direc



TIDE MOTOR.

tion in which such machinery will be operated during rise and ebb of the tide. The inventor intends to use this motor power to operate electric dynamo machines, which power may be transmitted through electric wires for electric lighting and for operating different elevated, surface and underground railroads, etc. The illustration gives a somewhat diagrammatic side elevation view of the invention

CARBURETER FOR INTERNAL COMBUSTION ENGINES.—S K Bradford, P O Box 74, Palo Alto, Cal. This carbureter is for use with gas or petrol motors, particularly such as are used on auto vehicles and aerial machines. A feature is the automatic adjustment of the needle valve such adjustment corresponding to variations of barometric pressure due to difference of altitude the principle of operation being the same as that of the ordinary aneroid barometer

MUFFLER.—V R Still, 65 Baker St., Patchogue N Y. A principal object here is to provide for the elimination of sound accompanying the discharge of exhaust gases from internal combustion engines by absorbing the heat of the gases and thereby reducing the expansive force thereof to avoid back pressure on the exhaust of an engine of this character

Railways and Their Accessories.

CAR COUPLING.—B. Zuckerman, 612 Eleventh Ave, Manhattan, New York, N Y. The principal object of this invention is to provide a car coupler made up of few parts which, however are adapted to coöperate with one another in a secure and efficient manner whereby a new and improved structure of this class is provided. The coupling is automatically performed

TRACK ATTACHMENT FOR SWITCH SIGNALS.—H H Rice, care of Depot Quartermaster, U S A, Honolulu, Hawaii. This invention relates to safety appliances for railways and has particular reference to devices for signaling or giving indication to the locomotive engineer of the fact of an open switch, draw or the like which would be a menace to the train approaching the same.

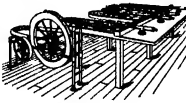
RAILROAD TIE.—J H May, 204 C St. Napa Cal. This tie is a shock-absorbing tie of reinforced concrete and will stand heavy traffic and in carrying out this feature the absorber operates to absorb a large portion of the shock and this together with the reinforcement of the tie provides one which will stand wear without breaking and will prevent rails from spreading.

Pertaining to Recreation.

GAME APPARATUS.—B. Kranchen, 416 62nd St., Brooklyn N Y. This apparatus comprises suitable devices for throwing a movable member representing a ball, and striking said member after being thrown, so as to propel it in different directions across the board, upon which is represented a base ball diamond having bases and base paths and provided with figures representing players.

SNELL FASTENER.—P H. Kimsey, 92 Harrison Place, Brooklyn, N. Y. This fastener is provided with a spaced line retaining hooks for engagement with the line and a snell retaining hook for engagement by the loop of the snell and arranged intermediate with said line-retaining hooks and extending in a direction opposite to the one of the line-retaining hooks.

GAME APPARATUS.—A Reibstein, 48 Stuyvesant St, New York, N Y. In this case use is made of a series of game tables shown in the illustration, an inclined runway extending in front of the tables, ball-impelling devices mounted at a right angle to the runway opposite the tables to permit of shooting a ball traveling down the runway off the latter



GAME APPARATUS.

and onto a corresponding table. Use is also made of a return chute connected at one end with a lower end of the runway and having branch chutes arranged adjacent the tables, and a driven wheel for receiving the balls from the chute and delivering them both to the beginning end of the runway. The invention relates to game apparatus in Letters Patent of the U S No. 1,018,342, formerly granted to Mr Reibstein

Pertaining to Vehicles.

SPRING WHEEL.—F W Brown, 507 Denegre Bldg. New Orleans, La. The purpose here is to provide a device which will simulate closely the action of a pneumatic tire and which has advantages that the pneumatic tire does not possess. Also to provide a wheel so arranged that portions may be easily taken apart or assembled.

WHEEL.—A McKillop, Downieville, Cal. This invention is an improvement in wheels, and has for its object the provision of a simple strong light weight wheel wherein is provided a pneumatic cushion between the spindle and the tread protected on all sides from ex

WHEEL.

ternal injury and imparting to the wheel a great amount of resiliency while of small size and inexpensive. The accompanying illustration shows a vertical section of the invention transverse to the plane of the wheel.

Note. Copies of any of these patents will be furnished by the Scientific American for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

---

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents subscriptions, books etc This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12730) F D asks I am trying to make small dry batteries Would like to try the formula for Dr C Gassner's dry battery on page 407 of your book Experimental Science by G M Hopkins, edition year 1899 and find the word plaster 3 parts etc used Now please tell me what is plaster? A. The formula given in Experimental Science for Gassner dry cells is the same as is always used in this form of dry cell By plaster is meant plaster of Paris This is bought dry and is stirred up with the other materials and the water when the cell is to be filled This makes a wet paste which while soft is rammed into the space between the zinc and the carbon When the plaster sets the whole is firm This formula is a reliable formula. We do not know any better although there are cheaper It is also to be found in SUPPLEMENT No 792 price ten cents

(12731) W T asks Two men circling a given point keeping the same distance from given point A moving on circle 4 feet from given point B moving on circle 3 feet from given point and always keeping given point between them After each has circled the point once has A circled or gone around B? A The problem of the men going around in a circle at different distances from the center and the question Do the men go around each other? is very old It has numerous forms The squirrel on a tree trunk and the hunter walking around the tree while the squirrel goes around the trunk is perhaps the most common The moon and the earth is exactly the same as you see Does the moon go around the earth and the earth go around the moon? Astronomers answer yes We have always answered all these questions Yes The answer depends upon the answer to the question What is meant by the phrase to go around? We answer that by saying that a person goes around another if he is at one time to the east of the other and in turn passes around him so that he is to the south west and north and finally is to the east of him again whether the other party has stood still or not then he has been around that other person Apply this to each of the two men in your case and if you accept our definition you can answer the question as well as we can for you If you do not agree with us upon the definition of going around we shall not agree upon the answer to your question There is no need of debate There is only need to agree upon the definition of the terms employed

(12732) C C asks 1 How much gas is produced by one pound of carbide? A One pound of carbide is rated to give 4 cubic feet of acetylene gas at normal pressure 2 How much from a gallon of gasoline? A The gas from gasoline as used in the gasoline engine is a mixture of gasoline vapor with common air Very roughly about 1 800 cubic feet of air-vapor mixture of proper composition to give good explosion power may be produced from a gallon of gasoline 3 How long does it take for the world s population to double itself? A It is not possible to give more than an estimate of the rate of increase for the inhabitants of the whole world, since a considerable fraction of the world s population has never been enumerated The population of the United States increased 21 per cent in both the last decade and the one preceding the last Figures can be given for the countries of Europe much of South America and for the British colonies. 4 Is there anything known that will double the yield from the land? A A better agriculture will increase our crops immensely We are by no means at the end of our resources in this respect We are just starting to learn how to farm See an article in SUPPLEMENT 1930 price ten cents entitled Plant Food in Relation to Soil Fertility in which there is much valuable information 5 If not is there enough new land to keep the increasing population and animals in the present standard of living till the middle of this century? A Untilled land does not bear so large a ratio to tilled land as to enable the increase of population to be provided for by bringing new land into cultivation for an indefinite period although the end of things is not so near as you state 6 Or does the world grow? I think it does, because if we add layers to a ball it must get bigger and are not the old cities forests, etc found deep down grown over by falling vegetable and other matter? And does that not explain why lakes and streams disappear? Are they not filled up by this matter as the earth grows, and the water sinks in to the earth? A The earth does not grow in the sense in which you seem to use the term. The materials which have covered forests, cities, etc are not additions to the earth from outside, but are simply the result of changes in the materials of the earth itself perhaps in the very neighborhood where they now are. Mountain sides are washed into the valleys by the streams, vegetable and animal forms grow [illegible] and decay, to be covered and forgotten, the sediments harden into new rock strata, a [illegible] [illegible]

which entered into them, all derived from the earthy matter already in existence before they were formed and still existent in the new forms.

(12733) F. R. asks: Please advise us why razors and other steel tools lose their edge and when laid aside without sharpening seem to regain their original keenness. There has been an old saying that a razor or certain other tools after being in use for some time get tired and if laid aside for a time take on courage and can be again successfully used without practically any sharpening. Is this really so? A. We have no knowledge whatever as to the regaining of its original sharpness by a razor which once dulled has been laid aside. Ours do not act in that way. We have to hone them again or send them away to be sharpened. The greater likelihood is that steel-edged tools will become dulled by rust if there is any chance of moisture being upon their surfaces when laid away. For this reason men are usually advised to hone their razors after shaving and before putting them into their cases so that the friction of honing may dry the edges and drive off the moisture which is certainly there after using them in the lather. We cannot say that we think your theory is really so.

(12734) G. M. asks: 1. Would you kindly notify through the columns of your paper the process by which I could take photographs on paper, the same to be used as a negative from which other prints are to be made? The pictures to be small but numerous. A. You can make negatives upon Velox and other developing papers just as positives are made. These negatives may be rendered semi-transparent by rubbing glycerine over the back and then they may be used for printing positives as other negatives on glass or celluloid are used. They will however probably show the grain or web of the paper in the positive and not be as satisfactory as negatives made upon a film of celluloid. The ordinary Kodak film or any other similar film is far better adapted to the purpose than paper and we would strongly advise against the use of paper unless you have some reason for its use which you do not state in your letter. 2. Could you also give the process by which pictures are transferred from paper to paper? I have seen a paste for doing this work but I am unable to get any information about same. A. We do not know any process for transferring photographs by means of a paste or other adhesive to another piece of paper. If the photograph be fixed upon a card or thick paper by glue or paste you may perhaps be able to wet the paper and rub it off with the finger as in some other transfer processes. You will find these given in our Scientific American Cyclopedia of Formulas, which we send for $5. We shall be pleased to receive your order for a copy. 3. Could you also give a process for fireproofing thin paper? A. Borax or alum may be dissolved and paper may be soaked in the solution and after drying will be slow burning, indeed will not burn with a flame, but we do not know any mode of rendering paper non-burning or completely uncombustible. The various methods are given in detail in our Cyclopedia of Formulas referred to above.

(12735) T. A. P. asks: What is the name of the largest sun in the visible universe and what is its diameter and mass? A. No one knows which is the largest star nor what its size may be. The distances of only about 20 stars out of about 125,000,000 in all are known to a certain degree of accuracy. Perhaps Arcturus is the star which suggested the inquiry to you. He is a giant among the stars about which we have the more knowledge and is described in our SUPPLEMENT No. 809. Other articles upon the same topic are to be found in the SUPPLEMENT Nos. 1474 and 1658, price ten cents each. We send you our SUPPLEMENT Catalogue, which will give you the topics of many papers which you will surely find of interest. We can supply any number mentioned in this catalogue at ten cents each.

(12736) J. B. M. asks: 1. Where can I obtain an explanation of the principle on which the stereoscope works, showing exactly how the rays of light operate to make the stereoscopic effect? A. Stereoscopic views are made by the use of a camera with two lenses as far apart as the eyes of a person. They are, therefore, the same as the views seen by the right and left eyes. These are mounted side by side on a card. The lenses of the stereoscope are as if cut from the sides of a larger lens and are therefore somewhat wedge-shaped. They bend the rays of light apart, each using only the light from its own view, and in such a manner that the eyes see the two views in the same place in front of the lenses combined into one view. The textbooks of physics, used in the schools and colleges, usually have a paragraph about this instrument, with a cut showing the paths of the rays of light. You will probably have no difficulty in finding the information in some textbook or encyclopedia in the public library of your city. 2. Do you know whether there has been any successful attempt to produce the stereoscopic effect on a screen so it can be viewed by an audience? A. The pictures of the stereoscope have been many times projected by two lanterns, one over the other, but [illegible]

NEW BOOKS, ETC.

THE COMPLETE YACHTSMAN. By D. Heckstall-Smith and Capt. E DuBoulay With 200 illustrations in the text and 24 plates. Size 5¼ × 8¾ in., 503 pp. Price, $3.75 net. New York Outing Publishing Company

It does not take an expert yachtsman to realize that within the half thousand pages of this volume must be contained an answer to the thousand-and-one questions which are liable to be asked by the yachtsman for his guidance and instruction in the noblest of all pastimes. The writer has had some knowledge and experience in the owning and sailing of boats and yachts and he did not need to read very far in the pages of this volume to realize that here was a most admirable and greatly needed work. The halftones are among the best that we have seen of notable yachts under full sail. Starting with the embryo yachtsman taking his first lesson in the rudiments of rowing and sailing the reader is carried throughout the whole range of the subject from open sailboats through the knockabout, the sloop, small and large to the two-masted schooner and is told more about their construction and handling than it is given to the average yachtsman to acquire in a lifetime As an instance of the high quality of the book and the extremely interesting way in which technical information is imparted we draw attention to Chapters 12 and 13 in which no less than forty pages are devoted to a detailed description of the varying fortunes of a race among first-class racing sloops over a thirty-mile triangular course. The many problems involved in the handling of a big racing cutter of the modern type are brought out in a most fascinating and readable way Many yachtsmen will feel that these two chapters alone are well worth the price of the book

AUS DER GESCHICHTE DER MENSCHLICHEN DUMMHEIT München Albert Langen, 1912.

Dr Kemmerich has written a book which is not only an interesting historical document but a most effective piece of satire, effective because it presents incontrovertible facts in a way that sets forth most tellingly the vanities the follies and the mean mistakes of mankind There is some crumb of comfort in the fact that since most of Dr Kemmerich s instances of human stupidity are taken from the Middle Ages, we can explain them away by arguing that they were the superstitious products of superstitious times and therefore hardly applicable to human beings of to-day We could wish therefore that Dr Kemmerich had given more modern examples of obstructions to progress. The whole literature of evolution for example, is replete with them To be sure in the latter portion of his book Dr Kemmerich does devote some space to modern superstitions. The devil he assures us, is still the object of much concern even in the year of grace 1912 Perhaps the most shining instance of modern stupidity is that of people who bury themselves alive in order to escape the census taker When we laid the book down we wondered whether it was not more a history of human insanity than of human stupidity

HANDBUCH FUER HEER UND FLOTTE Enzyklopaedie der Kriegswissenschaften und verwandter Gebiete Herausgegeben von Georg von Alten. Berlin Deutsches Verlagshaus Bong & Co , 1912.

Installments 49 and 50 of the ' Handbuch fuer Heer und Flotte cover the first part of the letter G The longest discussion to be found in these two installments is that which relates to fighting (*Gefecht*) A very compact and valuable review of old and modern methods of fighting both on land and sea is here presented Under General will be found much valuable information on such topics as General War Fund Lieutenant-General and other military titles in which the word General occurs. Of the geographical articles, that on Genoa is the most complete and therefore the most valuable.

TRIUMPHS AND WONDERS OF MODERN CHEMISTRY A Popular Treatise on Modern Chemistry and Its Marvels. Written in Non-Technical Language for General Readers and Students. By Geoffrey Martin. New York D Van Nostrand Company, 1911. 340 pp , 76 figures. Price, $2 net.

The sensational and the bizarre are attractive to most minds, it is very generally believed that to most minds they are injurious. It is no doubt because of these opposed reasons that the pronouncements of advanced scientific thinkers, reconnoitering beyond the outposts of learning, are read with avidity by the layman, and torn to pieces with equal avidity by scientists of more staid and sober thought. It is but seldom that a writer dealing with highly theoretical matters becomes neither a partisan nor an antagonist.

Into the realm of speculation, the reader is at once led by Mr Martin. The excursion is an interesting one, though a trifle bewildering, since billions are about the smallest numerical magnitudes dealt with. While we perhaps differ with the author's positiveness in stating that certain so-called molecular, atomic, and corpuscular conditions and relations are so, rather than that they are indicated to be so by more or less [illegible] evidence, we think his store of data collected, and his manner of presenting it, of interest and of value in showing the trend of modern experimentation and the speculation based upon it. While his applications of physico-chemical principles to the conditions of life on this earth show the wonderful inter-relation of [illegible]

and the language throughout is scholarly and exact. Occasionally there is a somewhat misleading lack of exhaustiveness, due beyond doubt to the author's desire to avoid confusing the reader unfamiliar with the detail of chemical knowledge. If any serious criticism is to be made, it is of the too frequent insertion of poetry in the body of the work Vague and inexact poetical expression can seldom be useful in illuminating accurate scientific concepts.

The book will be read with interest by chemists because it carries them beyond many familiar points the novice can read it because it will arouse his interest and hold his attention It is in no sense a systematic textbook it was not intended for one but rather a stimulus to the desire for systematic chemical study

THE CURTISS AVIATION BOOK By Glenn H Curtiss and Augustus Post. With Chapters by Capt Paul W Beck, U S A, Lieut Theodore G Ellyson, U S N, and Hugh Robinson New York Frederick A Stokes Company, 1912

Following the example of other designers and operators of flying machines Mr Curtiss has, with the able assistance of Mr Augustus Post, given us a very readable account of his life and of his rise as an inventor of aeroplanes. In reading this book one cannot fail to be struck by the fact that Mr Curtiss's experience in the building of motors for motorcycles and his record-breaking achievements as a motor-cyclist stood him in good stead as an apprenticeship for the career with which he was subsequently to become identified Of technical information the book contains very little for the very good reason that it was obviously written for the general public rather than for the constructor of flying machines. To our mind Mr Curtiss's principal contribution to the art of flying has been the development of the hydro-aeroplane To him more than to anyone else, we are indebted for a new type of air craft which promises to broaden the scope of flying and to place the aeroplane within the reach of those who would like to fly but only if it can be done with safety It is true that Fabre must also be considered a pioneer in this art but we believe we are correct in asserting that to Curtiss we owe the real flying boat It is therefore a pleasure to find that an appreciable portion of the book before us is devoted to Mr Curtiss's work with hydro-aeroplanes

NATURE'S HARMONIC UNITY A Treatise on its Relation to Proportional Form By Samuel Colman, N A Edited by C Arthur Coan, LL.B With 302 illustrations by the author New York G P Putnam's Sons, 1912 8vo, 323 pp Price, $3 50 net

The author's thorough and fascinating research discloses a marvelous harmony among those laws of Nature which govern proportional form Is it too much to suppose that the rules adopted by artists and architects among the ancients were based upon a close observation and a sympathetic interpretation of those natural laws as manifested in crystal in flower and in shell? Several interesting works tend to uphold this theory notably those of Prof A H Church of Oxford and Prof Raymond of Princeton University But no work has hitherto been issued which so graphically shows the connection between the laws of Nature and Art or which comes so near to a demonstration of the application of Nature's constructive principles to works of art While emphasizing the element of measurement in imaginative construction the author points out that while music is the most mathematical of all the arts yet it is also the one which leads the mind most persistently to the highest realms of imagination and emotion Poe said that poetry was one tenth ethical but that the other nine tenths of the art appertained to mathematics In the work in hand the illustrations have been planned and wrought out with great care The section on architecture is perhaps the most interesting both from the value of the applications therein made and the beauty of the illustration The relations between the proportional dimensions of a snow crystal and those of the Parthenon are strikingly shown Altogether the work is one of singular beauty and inspirational power

FRESH AIR AND HOW TO USE IT By Thomas Spees Carrington, M D New York The National Association for the Study and Prevention of Tuberculosis, 1912 8vo, 250 pp, illustrated Price, $1

HEALTH IN HOME AND TOWN By Bertha Millard Brown, S.B New York D C Heath & Co, 1912 8vo, 312 pp, illustrated Price, 60 cents

In this time of awakening to the advantages of outdoor life, and the growing prevalence of outdoor sleeping "Fresh Air and How to Use It" will appeal to a wide circle of readers. It contains chapters on ventilation, on wall houses and iron-frame porches for city use on permanent sleeping porches and loggias and the methods of protecting and screening them and on tents and tent houses. There are many illustrations, showing all manner of devices for securing fresh air, particularly during sleep The final chapter discusses clothing bedding, and furniture, with the various forms of sleeping bags and tent cots. "Health in Home and Town" is, as its title would indicate, a little broader in scope and a little less detailed in description. Besides the matter of securing fresh air both night and day it takes up such important features of our lives as running water in the home, methods of heating and lighting the care of the home, parks and playgrounds, food supply city water and ice, refuse, dangerous diseases, and the prevention of disease, particularly of tuberculosis. Both books may be commended to those who would improve the conditions of life and raise the standards of health and happiness.

"The Whip" and Its Mechanism

(Concluded from page 98.)

lar device is in use on the other side of the stage to give the effect of the exhaust of the automobile which is racing to save the life of the precious horse. The steam exhausts into a large packing box and the effect is very realistic. There are electric lights at intervals along the track which are flashing in succession, thus giving the effect of the light from the cars on the rails. A moving panorama at the back rounds out the illusion. The tunnel consists of a black cloth scene and it is set in semi-darkness by men who wear black smocks so they will not be seen by the audience. This is a variation of the well known trick called "Black Art." When the locomotive is pushed forward by the men propelling it, it is run up on an interrupted inclined plane. The slats which have been removed at the top of the plane leave an aperture which receives a false wheel in the center of the locomotive that throws it over to one side. The locomotive, which is built of wood, is piped so that steam comes out of the stack, fire box and underneath. At the moment of the crash a bomb is exploded in the box car and it is promptly broken by men who pull lines at a signal.

The scene gives an admirable idea of what English rolling stock really looks like from the inside, but the privileged few who have been taken behind the scenes and ridden in the coach (a much sought for privilege) will all concur in saying that there is no coach in England as hard and unyielding as is this theatrical property. It would almost appear preposterous to those who have not been abroad or have seen the play that an evil minded person could emerge from his compartment and creep along the footboard to work such mischief, but some of Europe's most atrocious crimes have taken place in railroad passenger carriages of this type.

"The Whip" was sent to Newmarket by another train and after strenuous unsuccessful attempts to prevent her being ridden by her own jockey, the actual race takes place. The stage has been cleared of scenery and those who have taken part in the mob scene gradually edge off to left and right. The stage is darkened for a moment, the curtain is raised, and the audience sees for a brief moment a most exciting race. There are eight horses in the race, but there is a chance for only two of them to win, as the others are held in position by iron rods which prevent them from actually progressing across the stage. In order to give a lifelike appearance they run on treadmills which are flush with the floor of the stage. The treadmills of "The Whip" and her nearest competitor are mounted on rollers and are adapted to move across the stage in a channel which is provided by removing sections of the flooring. Two men in the cellar receive a cue from a man who is watching the race through a hole in the floor, and at the proper signal they both turn their winches and at another signal the removable platform on which "The Whip" is speeding is drawn forward past the winning post, which is mounted on rollers and is pushed back at the critical moment by a man who stands behind it. He is masked by a black background which serves to bring out the winning post in relief. The panoramas which run in the opposite direction to the race are extremely ingenious. The large panorama is fixed and occupies the back of the stage and this is driven by a 35 horse-power motor in the cellar. The other four panoramas, however, which prevent a sharp line of demarkation, can be pushed around into position, and each of these four panoramas is actuated by its own motor. The five panoramas are all controlled through one switchboard so that they are all moved in unison.

The horse race on the stage is not a new thing by any means, the first of such devices being used many years ago in a melodrama called "Paris Port de Mer." Neil Burgess obtained a patent on the mechanism for accomplishing this effect and it was also used in "Ben Hur." It was found in "The Whip" that by sinking the treadmills so they are flush with the stage, it was not essential to run moving belts in front of the treadmills as was necessary even at Drury Lane. The idea of having the small portable panoramas is a very good one, as it adds a great deal to the realism.

It is very unusual to get permission to illustrate stage mechanism by actual photographs and we are indebted to the Drury Lane Company of America, its directors, William A. Brady, F. Ray Comstock, Morris Gest, and Mr. Arthur Collins of London, with whom special arrangements were made, and Mr. Ben H. Atwell, who conducted the negotiations.

The Mercy of Steel and the Menace of Wood

(Concluded from page 90.)

picture of those which we present in illustration No. X, showing a steel day coach after it had assisted in completely demolishing the two wooden cars to the rear and in front of it. This car passed through the frightful collision on the Delaware, Lackawanna and Western Railroad near East Corning, New York, on July 4th, 1912, when an express train, disregarding the distance and stop signals, crashed at sixty miles an hour into the rear of an express train ahead of it. The energy of the colliding train was expended mainly on the last three cars of the train ahead. The rear car was a wooden day coach, the next was a steel coach, and ahead of that was a wooden sleeping car of very strong construction. The flagman of the stalled train went back some two thousand feet from the rear of his train, put a lighted green fusee on the end of the tie on the engineman's side of the track, waved his flag, but did not, as he should have done, place any torpedoes on the rail as required by the rules during foggy or stormy weather. An eight-car express train running sixty miles an hour swept round a curve, disregarded the distance and home signals, the flagman's flag and the green fusee, and swept straight ahead. The engineer was busy with his injectors, which were out of order, and when he passed the flagman was observed to be looking not ahead but across the boiler. The rear wooden car, caught between the upper and nether millstones of the engine and the steel car, was reduced to matchwood, as shown in illustration No. IX. In acting as the anvil for this mighty blow of nearly 70,000 foot-tons the steel car suffered no worse injury at its after end than the crushing in of the platform. Driven forward by the impact, it reduced to unrecognizable wreckage no less than two thirds of the heavy sleeper ahead. In doing this it suffered the injury shown at the left end of the car in illustration X. Beyond the fracture of windows, the main body of the car, as can be seen from the photograph, is practically intact.

An automatic stop set 1,000 feet back from the home signal would have averted this wreck, in which 40 people were killed and 88 injured.

Summing up, then, we may say that the lessons taught by the accidents we have had under review are mainly three. First, the imperative necessity of changing the practice of our rail mills so as to absolutely eliminate rails that are piped or otherwise defective; second, the substitution, as quickly as financial and other conditions will allow, of steel for wooden cars; and, last, the universal adoption in connection with the present block signal system of the automatic stop.

A Fire-resisting Envelope.—Harry H. Jensen of Oakland, Cal., has patented, No. 1,046,467, an envelope-like receptacle which has a fire-proof layer and a finishing layer with a carbon sheet between such layers by which marks of identification produced upon the finishing layer may be transferred upon the fire-proof layer, so that in case the finishing layer and the transfer layer are destroyed, the identifying marks on the fire-proof layer of asbestos will serve for identification purposes.

The Mysteries of Artesian Wells

ARTESIAN basins, or the underground water supply which furnishes artesian wells with their constantly flowing streams sometimes spouting to a considerable height above the surface are often popularly referred to as subterranean rivers which are believed to flow at great depths eventually finding their way to the surface to feed some visible stream. Or they are thought to exist as great caverns or reservoirs deep down in the earth which if tapped by the drill furnish the tremendous flows of water which characterize some of our largest artesian wells—several hundred thousand and even in some cases half a million gallons a day. It is true that artesian waters are stored up in underground reservoirs but they are not of this character. Most artesian water supplies consist simply of water filled strata of sandstone or other porous rock material through which the water very slowly percolates confined from above and below by other strata of impervious rock or clay. Through this inclosed layer of porous rock the water works its way with infinite slowness following the dip or slant of the rock and where tapped coming to the surface if the surface at this point be below the source of the supply. Coarse sandstone is capable of holding a great quantity of water as much as 8 quarts per cubic foot but the rate of its movement through this rock is so slow as to be almost inappreciable.

To illustrate how slowly the water travels. Many artesian or flowing wells are found along the Potomac River at Colonial Beach and other points in Virginia about 60 miles south of Washington. This water is obtained by drilling into a sandstone formation which extends along the Potomac Valley and into Maryland and outcrops near Frederick, Maryland some 50 miles north of Washington. It takes about 100 years for the water of this subterranean river to flow that distance that is the rains falling upon the exposed portions of the porous rocks near Frederick sink in and move southward at the rate of about 1 mile a year. The water bubbling from the wells at Colonial Beach today fell as rain on the uplands and mountains of Maryland around about the time that Washington was President of the young American Republic.

Ozone as a Rapid Paint Dryer

PAINT drying has no connection with the evaporation of water. In fact the weight of the painted surface increases in drying. Paints are mixtures of insoluble pigments or coloring matters with some drying oil generally linseed. When exposed to the air the oil absorbs oxygen and is converted into a smooth elastic mass called linoxyn.

To hasten this drying process the oil is frequently boiled before mixing with the pigment. Lead oxide, manganese dioxide or metallic salts are added in the boiling process to start the drying or oxidation of the oil. The oxides give up their oxygen but the salts act as oxygen carriers. The most recent accelerator used in paint drying is a blast of ozonized air. Ozone is only a more active form of oxygen obtained by passing air through the silent discharge of a high voltage electric current leaping across a gap. Machines are on the market at a low price that furnish large quantities of ozonized air and the cost of operating is no more than for one or two sixteen candle power lamps. They are portable and easily attached to ordinary lighting circuits.

Since ozone oxidizes with enormously greater speed than oxygen its value in paint drying is evident. In the painting of automobile bodies hurried drying is demanded by the crowded condition of the factories. Recent tests with ozonized air showed after two hours an increase in weight of the painted body of 3.34 per cent, while with ordinary air the corresponding increase was only 1.51 per cent. This increase was due to the absorbed oxygen, and fairly measures the relative [illegible] of the two drying methods.

Water Supply

¶ To meet the pressing demands of five million inhabitants, New York has been obliged to undertake the most stupendous aqueduct system in the history of the world.

¶ Hampered by its situation on a narrow strip of land that intrudes between New Jersey and Connecticut, this, the second largest city in the world, has had to look to the north, and the north only, for its supply of water.

¶ In the heart of the Catskills an entire valley has been swept bare and converted into a lake 40 miles in circumference.

¶ From this reservoir runs an enormous conduit that dips into valleys and under rivers, pierces mountains and bores through solid rock, 1100 feet beneath the Hudson River, to the Croton Reservoir.

¶ Thence down through the heart of the city, so far below the surface that the busy people above give no thought to the daily firing of tons of dynamite, the conduit is being gnawed through solid rock.

¶ Finally a pipe line extension will pass under the waters of the bay to Staten Island, 127 miles from the source in the Catskills.

¶ The whole marvelous story will be told in the Scientific American of March 1st.

¶ Price 15c at all newsstands.

The Rock-removing Machinery of the Suez Canal

By Jacques Boyer

THE Suez Canal traverses a diversified country. Near Port Said it passes through argillaceous sand and a few large beds of more or less compact clay. The bed of Lake Timsah consists of a hard conglomerate of sand and limestone, between Lake Timsah and the Bitter Lakes occur loose sand, mixed with clay gravel and gypsum, and overlain by a layer of salt and other deposits left by ancient evaporation, finally, compact clay, marl, and sandy conglomerates alternate until the Red Sea is reached. No rock has yet been found except in the southern part of the canal between kilometer 85 and Suez. Here the outcrop of the rock is almost horizontal. It occupies an area of 300 000 square meters (3,229,200 square feet) in the bed of the canal. The rocks include limestone of greater or less hardness, calcareous and silicious conglomerates generally containing shells, red calcareous tufa, gypsum and alabaster. In general, the rock is of medium hardness, except in certain deposits of compact limestone and sandstone.

In the construction of the Suez Canal, the rocky portions were removed before the water was admitted. In 1884, when the company undertook the work of widening and deepening the canal, it became necessary to devise means of removing rock under water. The hardest rocks were shattered by submarine mines, and the softer ones were removed by apparatus composed of a battery of 10 steel rams, weighing 3.5 tons each, which were raised and let fall on the rock in the manner of pile drivers. These same were placed on a floating bucket dredge which removed the rock as it was broken.

Experience soon showed that the efficiency would be increased by separating the rock breakers from the dredge and placing them on special floats. Although this arrangement produced an appreciable improvement it still gave only a mediocre result because of the insufficiency in the weight of the breakers. From fourteen to sixteen blows per square meter were required to break up rock of medium hardness to a depth of ½ meter (20 inches).

In 1897, when it was decided to increase the depth of the canal to 9.5 meters (31 feet), the engineers of the company studied the question more thoroughly. They found that for the removal of rock under water, the method described above is more economical than drilling and blasting. Furthermore, the employment of explosives presents certain obstacles to the navigation of the canal. After each blast, for example, it is necessary to send down divers in order to make sure that the channel is not blocked by the shattered rock. The blasting method cannot be carried out on so regular a plan as the other, and it also involves the removal of an excessive quantity of rock in order to obtain the desired profile with certainty. A few years ago, therefore, the engineers definitely adopted a rock breaking apparatus provided with two spindle shaped rams of cast steel, 13.5 meters (44.3 feet) long and weighing 18 tons each. These rams terminate below in replaceable points of very hard steel. The two rams are placed a yard apart and are raised by powerful steam winches which operate almost instantaneously through very flexible steel cables permanently attached to the tops of the rams. By means of this arrangement it is possible to hoist the rams very rapidly and to regulate without difficulty the height of fall which ordinarily ranges from 5 to 10 feet. The two winches may be coupled in order to exert an exceptional effort upon a single ram which has become fixed in the rock.

The apparatus is mounted on a float 30.5 meters (100 feet) long 10.57 meters (34⅔ feet) wide and 2.44 meters (8 feet) deep, made entirely of Siemens Martin steel. The falling rams are guided by a frame of special construction which also carries the pulleys over which the cables run. The float is moved forward, backward and in any direction rapidly by means of a steam winch.

Fig. 1.—Fourteen ton rock-breaking ram

Fig. 2.—Placing in position the head of a rock breaking ram

Fig. 3.—Rock-breaking float at work on the Suez Canal.

This apparatus was put into service in 1902, and since a few improvements in detail have been made, it has operated perfectly and broken all kinds of rocks without difficulty. In 1908 a second apparatus was installed having two rams weighing 14 or 15 tons each and 15 meters (49 feet) long which operate to a depth of 12 or 13 meters (about 41 feet). As a rule, 132 blows are delivered in each working hour. The mean thickness of the layer of rock shattered is 0.8 meter (31½ inches). In these conditions the number of blows required to break a cubic meter of rock varies from one to forty according to the character of the rock. The average is about seven blows per cubic meter.

The output thus varies from 132 to 3.3 cubic meters (172.6 to 4.3 cubic yards) per hour with a mean value of 19 cubic meters (24.8 cubic yards) per hour.

Largest Embankment in Germany

AFTER eight years' strenuous work the Mauer embankment has been completed. This, the largest engineering monument of Silesia, and at the same time the biggest embankment in Germany is situated in the Bober Valley between Hirschberg and Lähn, at a widening of the river where the Bober describes a strong inflection.

The masonry dam has been erected on a rocky soil at about 60 feet depth, it is 106.8 feet in height and at the bottom of the river 164 feet in width and withstands a pressure of 440 920 000 pounds. The masonry on the side turned toward the water is provided with a cement coating reaching down to the ground, to prevent any water from penetrating into its interior.

The interior of the wall comprises shafts and galleries. It is at the surface 918.6 feet in length and 24 feet in width, and contains about 327 000 square yards of masonry. Being so exceptionally substantial the dam will, it is firmly believed, check the most dangerous of Silesian rivers.

Upward of the masonry dam an artificial lake 5.0 miles in length will be formed, the embankment controlling a precipitation area of 463.3 square miles. The artificial lake will be 600 acres in area and 153.8 feet in maximum depth.

This embankment will be utilized on a large scale for supplying power to a considerable district of Silesia. The huge power house stands close to the outside of the embankment wall and comprises four turbines each of 1 800 horse-power. As, however, this power house is connected with that of the Queis Valley embankment near Marklissa a total of 10 700 horse-power will be available which suffices to supply the whole district of Liegnitz with electricity for lighting and power purposes.

The embankment was inaugurated on the 16th of November in the presence of the Emperor.

Some Facts About Granite

GRANITE is two and two thirds times as heavy as water. Its specific gravity is 2.663. A cubic yard of granite weighs exactly three quarters of a ton. The strength of granite is tremendous, although the different granites vary greatly. Poor granites will withstand a pressure of 18,000 pounds to the square inch. Good, close-grained granite will withstand 30 000 pounds, but certain Wisconsin granites have withstood a crushing pressure of 43,973 pounds to the square inch—22 tons weight resting on a tiny cube of stone not much larger than a lump of sugar.

The purpose of this journal is to record accurately, simply and interestingly the world's progress in scientific knowledge and industrial achievement.

A Fatal Blunder

By remitting the tolls to coastwise ships that pass through the Panama Canal Congress has dealt a death blow to American deep-sea shipping. Everyone who has studied the problem of the decadence of our Merchant Marine understands that it is due to certain economic conditions over which we have no control. It costs so much more to build American ships and so much more to run them that successful competition with foreign ships in the deep-sea carrying trade is out of the question. That is a fact which no one disputes. Also it cannot be disputed that if we are to regain our former position as a leading maritime nation some form of Government assistance is necessary. Call it what we will, whether subsidy, subvention, preferential duties or what not, it is not denied and cannot be denied that Federal aid must be forthcoming, at least in the early stages of the upbuilding of our Merchant Marine.

Unfortunately, and thanks to the persistent misrepresentations of the stump orator and the yellow journal, there is a country-wide, though unwarranted, distrust of any proposed legislation which involves the principle of Government aid. The idea has been widely disseminated and too widely believed that Government aid represents nothing more nor less than the transfer of funds from the public treasury to the private purse of individuals and corporations.

Now the fatality of this matter of remission of Canal tolls lies in this, that to remit these tolls to the already prosperous and highly protected coastwise shipping companies is to do exactly what the yellow press has said would be done in every measure that contemplated Government assistance to shipping. To remit the tolls will be to make a free gift of $1.20 a ton to shipping companies which are already flourishing under the protection of a rigid monopoly.

So then the first attempt of Congress to give assistance to shipping will be a glaring example of that very abuse of the excellent principle of Federal aid, of which the country, thanks to misrepresentation, is so greatly afraid. With this preposterous act before their eyes it is certain that the people of the United States will become more firmly settled than ever in their unfortunate prejudice against any attempt, however commendable, on the part of the Government to assist in the reconstruction of our Merchant Marine. Not only has Congress given assistance where it is not needed, but it has killed for a long time to come any hope of assistance being given where it is needed.

The Complete Eradication of Typhoid

A MEDICAL contemporary has asked us to say something on the subject of typhoid eradication by immunization, and we gladly present the salient facts of this very vital subject.

One of the most important steps in the march of medical science has been the recent successful work in the prevention of typhoid fever by the use of typhoid vaccine. It has been demonstrated that inoculation will enable an individual, or whole regiments of soldiers for that matter, to live in typhoid-infected districts with complete immunity. It is not yet demonstrated just how long immunity will last, but it is known that protection is assured for at least one year. Typhoid immunization is harmless and in most cases causes no inconvenience.

Now the hope of the complete eradication of typhoid fever lies in the fact that the typhoid organism does not remain alive for any great length of time in water or the soil, two of the principal sources of the spread of the disease. Repeated investigation has shown that the typhoid bacillus will remain alive in natural water only for a comparatively short time; furthermore there is no evidence that the germ will live in soil longer than in natural water. Hence for the perpetuation of typhoid contamination in a well or some other water supply there must be added, at comparatively short intervals, fresh typhoid bacilli from a case of typhoid fever or from a typhoid carrier.

Now here are two facts of supreme importance: for if typhoid germs "will not survive more than a few months when exposed to the elements during warm weather," as stated by the *Bacterial Therapist*, and if "immunized individuals cannot contract the disease for a year or more," it follows that by carrying out systematic immunization during the winter months, there would be so few typhoid cases the following summer that the disease would be practically eradicated.

If a general typhoid immunization were carried out by the concerted action of the health authorities of the various States for a few years, there is every reason to suppose that the terrible scourge of typhoid would be swept out of the country. The State laboratories could furnish the vaccine at comparatively little expense. Would the public submit to the practice of general immunization? Thanks to the present-day widespread knowledge on this general subject, and the public familiarity with the results obtained in controlling other diseases, we believe it would.

Is not general immunization well worth a trial?

Some of the Absurdities of the Proposed Compulsory License Legislation.

MUCH solicitude is evinced in the report of the Committee to whom the Oldfield Bill was referred for consideration, lest the existing patent laws "enable owners of patents to withdraw a large amount of personal property from the control of the States." The Committee declares: "Nothing is more fundamental in our government than the clearly marked line between the jurisdiction of the State and of the Federal courts." Nevertheless the Committee recommends a scheme of compulsory license which gives every Federal district court throughout the United States power to hale before it every patent owner (except original inventors) whose invention, for any reason whatsoever, has not come into use within three years after the issuance of the patent, to determine judicially the value of the invention and to compel the patent owner to grant to any competitor who asks it a license to use the invention upon such terms as the Court may fix. This would transform the seventy-two Federal district courts into "courts of patent commerce." To quote one of the witnesses before the Committee, "for patents may cover collar buttons and steamships, tooth brushes and transportation systems, toilet articles and safety appliances, telegraph systems and tools, garments and foodstuffs."

How can the Committee reconcile such a proposal with its professed abhorrence of anything that may "ignore and override the jurisdiction of the State courts"? Such a scheme of compulsory license will diminish the inventor's market, enable any strong competitor to crush his weak rivals, impede every patent owner in developing and introducing his invention, retard the patenting of inventions and discourage the large-scale inventions and industrial experimentations on which civilization depends for solving the problems of existence.

To insure the non-enforcement of license restrictions, the substitute Oldfield Bill seeks to enforce solely against patent owners a Draconian code of business practice which is not and never has been imposed on any other class of property owners. Litigation under the Sherman Anti-Trust Act turns frequently, if not generally, upon close questions of law. By a salutary result of the existing law, property involved in all such litigation that is not in transit does not become forfeited if a combination in restraint of trade is found to exist. The substitute Oldfield Bill, however, provides that, under such circumstances, property in the form of patents shall be forfeited, while all other forms of property shall remain unaffected. Under the provisions of the bill the vendor of any patented article becomes a criminal if he attempts to secure a year's business, as a condition of selling to a retailer, if he attempts to hold the retailer to his agreement to buy his patented goods, exclusively or to a certain extent, if he attempts to hold the retailer to his agreement, to maintain a standard price on the patented goods; if he licenses the use of a delicate patented machine on condition that it be used only with specially prepared supplies, or in continuity with specially adapted machinery necessary to insure perfect operation, if he licenses the use of a patented machine with the requirement that a minimum royalty shall be paid and that all or part of the licensee's work shall be done on the machine, if he attempts to limit the licensees' use of the patented machine to a certain class of goods or a certain character of work to the end that he may be free to license to others the exclusive use of his patented machine on other classes of goods or character of work, if the quality of his patented inventions is used to induce licensees to take his machines, either exclusively or in part, for all their needs, if he agrees with a retailer in a town to sell his patented goods to no one else in the same town or to sell to other retailers only on less favorable terms, in consideration of which the retailer shall push the sale of the goods; if he licenses the use of his patented invention to a licensee who, for instance, makes steam engines of 1,000 horse-power whom he charges a rate of royalty different from that charged a licensee making steam engines of less than 1,000 horse-power, or if he sells the patented goods in a particular territory at a price less than that at which he sells elsewhere.

Any of these transactions, which good morals and honorable business practice to-day and from time immemorial have always sanctioned, is made by the bill conclusive proof of the violation of the Sherman Anti-Trust Act. The fact that the transactions might reasonably be shown to have no tendency to restrain trade, cannot save the unlucky patent owner, for the bill expressly provides that "restraint shall be conclusively deemed to have been or to be unreasonable and to be a violation of the provisions of said act" (i. e., the Sherman Anti-Trust Act) as to any one guilty of these transactions. The penalty which the patent owner may suffer for sinning in the manner indicated is the forfeiture of his patents, a fine of $5,000 and a year's imprisonment, and a payment of three-fold damages and the costs of suit and attorneys' fees to anyone who comes in within three years thereafter and proves any damage.

Was it a twinge of misgiving concerning this whole attainder of business, or was it an exquisite malevolence toward the patent system in particular, that suggested the imposition of these penalties on patent owners only? For the substitute Oldfield Bill forbids only patent owners from doing these things, and expressly leaves the owners of every other form of property free. Unlucky patent owners caught in the mesh may reflect that if they had dealt only in unpatented goods, instead of wasting time and money in developing new inventions, which their patents published to the world to the end that in seventeen years the world may use them without cost, they could have avoided all their misfortunes. Is this the way by which Congress is supposed to promote the progress of science and useful arts?

Machinery on the Farm

MENTION farm machinery to the average man and immediately he sees in his mind's eye a picture of ingenious harvesters, reapers, and binders. Perhaps, too, he may think of the tractor engine to which so much space has lately been given in illustrated periodicals, both popular and technical. But only if he be a technically informed man is it likely that he will think at all of the stationary engine and its agricultural possibilities, although it may be confidently asserted that it plays an even bigger part in transferring from flesh and blood to iron and steel the burdensome work of tilling the soil and harvesting crops. On many American farms little engines may be found that vary in size from one and two horse-power to forty and sixty horse-power, and that are used for almost every imaginable purpose.

Just how extensive is this application of engines it is difficult to state with any degree of certainty. No accurate statistics are available to show the actual number of farm engines in use, but the number must be huge. For example, in 1911 three companies alone made upward of 100,000 engines ranging in size from two to fifteen horse-power. Eighty-seven manufacturers reported that they had sold since starting in business, 655,000 engines, while seventy-six firms reported early in 1912 that their requirements for the year were at least 705,000 engines. As nearly as we can determine, there are seven hundred and fifty manufacturers of gasoline and oil engines in the United States, and fully five hundred of these make a specialty of farm engines. Their output must be at least half a million engines a year.

It is safe to assume that there are about two million gasoline and oil engines on our farms at the present time—probably a conservative estimate. The number is being added to at the rate of about 500,000 annually. The average size of these engines is about seven horse-power.

Every one of the 6,361,000 farms in the United States needs one engine at least, and many of them need two or three engines. Even under present conditions profitable use can be made of from thirty to forty million gas engine horse-power on the farms of this country. Surely here is an opportunity ready to be grasped by the enterprising manufacturer.

Engineering

Railway Construction in 1912.—During the past year there was added to the railroads of this country less than 3,000 miles of new line, according to statistics compiled by *Railway Age Gazette*. This is 845 miles less than the average for the past nineteen years. On the other hand, the total mileage of new line, commenced but not completed, is greater than it has been for five years past. Our steam railroad system is fairly complete, and it is natural to look for a decrease in new construction as the years go by.

The Artesian Wells of Australia.—The artesian well is one of the most important sources of water supply in Australia—a continent which is by no means lavishly supplied with the snow- and glacier-fed rivers which are so abundant in this country. A government report states that in 1911, in the State of Queensland alone, there existed 785 artesian wells, whose total depth aggregated 334 miles. Of these, 113 were over 3,000 feet deep, and one of them had been carried to a depth of 5,045 feet. Two of these boreholes, alone, gave a combined outflow of nearly 15,000,000 gallons daily.

Elasticity of an Alloy Spring.—One of the most important developments in metallurgy of recent years is the success which has been obtained with the various new alloys. We have before us the record of a test made on a vanadium-steel, automobile spring, which measured 56½ inches between centers and had a camber of 8½ inches. The spring was deflected under a load of 1,150 pounds to a straight line, and then under a load of 5,800 pounds it was deflected 15 inches. Finally, pressure was applied until the spring was reversed to what was practically a circle, without showing any sign of fracture.

Peat-producer Gas.—Chief B. F. Haanel of the Fuel Testing Division of the Department of Mines, Ottawa, has reported that the peat-producer gas-power plant has proved its reliability, since operation may be continued for a week or longer without shutting down for cleaning or overhaul. A test plant has been run for 1,0 hours continuously, and the report states that in regular service it should not prove necessary to clean the pistons more than once in several months. The output of the producer is uniform, fires can be cleaned without interference with the engine, and any operator of intelligence can run the plant.

Four-gun Turrets.—According to the Paris correspondent of *The Navy*, the two French battleships A-7 and A-8 to be laid down in 1913 will carry twelve 13.5-inch guns in three four-gun turrets. Are not the French putting too many eggs in one basket? One successful penetration by a high-explosive shell might put four guns out of action at once. Against this is to be considered the accuracy of fire and the considerable reduction of weight both in mount and armor. Our own three-gun mount embodies, we understand, a combined sleeve for all guns and the three guns will be given the same training and elevation under the hand of one man.

Important Railroad Electrification.—The Secretary of the Interior may be premature in his belief that the electrification of all the transcontinental railways is at hand, but he is certainly justified in attaching great importance to the grant by the Government of permission for the Great Falls Power Company of Montana to transmit over the public domain the necessary power to electrify 450 miles of track of the main line of the Chicago, Milwaukee and Puget Sound Railway in Montana and Idaho. In respect of the length of track covered, this is by far the most important application of electric traction so far made to a steam railroad.

A Notable Railway Bridge.—In this age of notable construction, work which only a few years ago would have commanded world-wide attention, now is apt to attract not much more than local interest and comment. A case in point is the handsome railroad bridge of the cantilever type, which has been built by the Pittsburgh and Lake Erie Railroad Company over the Ohio River, at a point about twenty-five miles below Pittsburgh. The total length of the bridge between back walls is 1,800 feet. The main cantilever structure, which measures 1,409 feet between centers of end pins, consists of a 370-foot end span, two 320-foot anchor arm spans, and a main span of the great length of 769 feet, which is made up of two 242-foot arms and a 285-foot suspended center span.

Twenty-five Knot Battleships.—The persistency with which the new 25,000-ton battleships for the British Navy are credited with a specified speed of 25 knots, raises the question whether the Admiralty has determined to merge the battleship and the battle-cruiser into one—a logical, and as it seems to us, a very sensible decision. Water-tube boilers, superheated steam, and the steam turbine have combined to render possible battleship speeds which could not have been thought of a few years ago. Our Navy Department has never favored the battle-cruiser, believing that our limited appropriations should be put into the first fighting line exclusively. England sets the fashion in naval construction, but if she builds 25-knot battleships, will the rest of the powers follow such a radical change?

Science

The Divining Rod Problem.—We learn from Count v. Klinckowstroem that a Society for the Elucidation of the Problem of the Divining Rod has recently been formed in Germany. The society counts among its members many men of prominence in the engineering and other professions and represents a serious scientific effort to shed light on a much debated question.

Storm Signals of the World.—The English Meteorological Office has just published a revised edition of the brochure entitled "Provisional Summary of the Maritime Weather Signals at Present in Use in the Various Countries of the Globe," which exhibits the remarkable diversity of the signals in question and is a strong argument in favor of the adoption of a uniform code. Hereafter this publication will be revised and reissued annually as long as various codes are in use.

An Aeronautical Weather Station has been established at Bitterfeld, Germany, by a local firm engaged in the construction of aircraft, and has been placed under the direction of a competent meteorologist, Dr. H. Rotzoll. Information for prospective travelers in the air is furnished on the basis of the twice-daily telegrams of the Deutsche Seewarte, at Hamburg, and whenever necessary pilot-balloons are sent up to ascertain the direction and force of the air currents over Bitterfeld.

A Great Collection of Hebrew Literature.—The last report of the Librarian of Congress contains an account of the Deinard collection of Hebraica presented to the national library last year by Mr. Jacob H. Schiff, of New York. This collection was brought together during many years by Ephraim Deinard of Arlington, N. J., and numbers 9,936 volumes and pamphlets, which cover a period of nearly three and a half millenniums, from the beginning of Hebrew national life to the present day. It is naturally very strong in biblical and rabbinical literature. "It forms," says the report in question, "an admirable beginning of a department of Semitica in the library, which the librarian hopes will develop into one worthy of the national library of a country in which the Semitic race is playing so important a role."

Using the Philippine Scouts to Fight Rinderpest.—The Veterinary Division of the Philippine Bureau of Agriculture is waging an energetic campaign against rinderpest, a disease which in former years destroyed annually upward of half a million cattle and carabaos in the Philippines, though the number has now been reduced to two or three thousand. A unique feature of this campaign is the extensive use made of the Philippine Scouts in searching for cases of the disease and also in patrol duty to prevent the introduction of infected cattle in regions where the disease has been stamped out. Last year a cordon of about 1,400 scouts gradually pushed southward as far as southern Pampanga and northern Bulacan, leaving the territory behind them free from rinderpest. About 150 of the Philippine Constabulary were utilized in the same undertaking.

A Novel Explanation of Glacial Periods was propounded by Prof. W. J. Humphreys, of the Weather Bureau, at the Cleveland meeting of the Astronomical and Astrophysical Society of America. Several times in recent years it has been observed that great explosive volcanic eruptions (Krakatoa, Pele, Katmai) by charging the upper atmosphere in the isothermal region with fine dust, have markedly diminished the amount of solar radiation received at the earth's surface. It seems evident that the effect of this process must be to reduce the temperature of the air near the earth, since the dust scatters a much greater amount of the solar radiation received from without than of the terrestrial radiation received from within, owing to the greater average wave-length of the latter. Thus a period of excessive volcanic activity if long continued would produce the thermal conditions of an ice age. The geological record furnishes evidence that such a period actually began shortly before the last ice age and has continued with diminishing intensity to the present time.

A New Idea in Storm Signals is now being actively discussed in the meteorological world. Heretofore various forms of flags, cones, drums, lanterns, etc., have been used to warn seamen that a storm is in prospect at the place where the signal is displayed, together with information as to the direction from which the wind is expected to blow in the same locality. These signals are well adapted for use in temperate latitudes, where storms are of great area. In the case of tropical cyclones, however, such as the West India hurricanes and the typhoons of the Far East, they do not give all the information desirable. If a vessel is about to leave port in these regions, the master wishes chiefly to know whether he is likely to encounter a cyclone along his route. A system of signals has been devised by Rev. L. Froc, director of the Zikawei Observatory near Shanghai, and is now in use experimentally on the China coast, which gives notice of the occurrence of a cyclone anywhere over the adjacent seas, together with its probable course. The International Meteorological Committee is considering the adoption of a uniform code of such "non-local" storm signals for use in all tropical countries.

Automobile

International Test for Motor Sleighs.—The Imperial Automobile Club of Russia has organized an international test for motor sleighs to take place in the environs of St. Petersburg on January 19th. The trials will include driving over five versts of snow-covered road and three versts of loose, untrodden snow. The first three of each trial will then compete in a special speed trial over both courses.

Acetylene Tank for Horse Wagons.—Partly with the idea of making the roads safer for the automobiles and their owners—who, of course, are the best customers of acetylene gas tank makers—one of the largest of these companies has brought out a miniature tank for use on horse-drawn wagons. The installation is similar to that on automobiles, the only difference being the size and number of the lamps required. One charging of such a tank will last for fully a month of ordinary daily use.

Rotary Motor for Automobiles.—While the rotary gasoline motor has proven a decided success in aviation, its use in automobiles has met with very little encouragement so far. Several systems have been given trials, but little has come of the attempts to adapt them for automobile use. The latest of them is the product of two Dutchmen who are at present in this country endeavoring to enlist the help of some of the large manufacturers. The motor is of the four-cylinder, two-cycle type, and so simple that the complete car, it is claimed, can be built for $400.

Carrying Motorcycles on an Automobile.—The new automobiles ordered by the German government have been fitted with "side pockets" large enough to accommodate two motorcycles, and have given a good account of themselves in the recent maneuvers. Entrance to the tonneau is effected from the rear and the running boards of the automobile are utilized as storage spaces. The particular advantage of this arrangement is that, as long as the car is running well, the cycles are out of sight and do not interfere with the free movement of the passengers. Should anything happen to put the car temporarily out of position, no delay would occur in the delivery of messages, as the motorcycles would be immediately made ready and mounted by two members of the automobile crew.

Selling Polish at a Show.—Some of the exhibitors at the recent London automobile show were ingenious to say the least, and one of them chose a novel means to keep his product in the public eye, or rather memory. At the stand in question metal polish was exhibited and samples were distributed. A man at one end offered small sample cans, but he was standing on a metal platform connected with a small induction coil. Those who stretched forth eager hands for the samples received a gentle jolt. Those who were eager enough for a sample and who could overcome their timidity were presented with them from the other man, minus the shock. The theory of the game was that it set people thinking. They remembered the shock and the remembrance brought to mind that particular brand of metal polish. Some time or other the recollection led to a test of the polish. The remainder is obvious.

$10,000 Prize for New Motor Fuel.—In order to encourage inventors and chemists, the British Society of Motor Manufacturers and Traders has offered a prize of $10,000 for a volatile fuel suitable for use in internal combustion engines. The only restriction in awarding the prize is the requirement that all the raw material or ingredients be obtainable in the United Kingdom in large quantities, so as to make Great Britain independent of other countries in so far as motor fuel is concerned, and that the fuel can be manufactured at a commercial price. The offer is the direct outcome of the present agitation for the improvement of carbureting devices and the alarming increase in the price of gasoline. The value of the prize itself is, of course, very small when compared with the enormous royalties to be derived from a truly satisfactory process of producing the desirable hydrocarbons. It is merely an encouragement in investigation.

Curing the Smoke Evil.—With the practical necessity for eliminating the smoke nuisance and the efforts of very nearly every engine manufacturer turned in that direction, some tests recently conducted by the Royal Experiment Station for Testing Materials at Berlin are interesting. A sample of commercial motor lubricating oil was separated into two portions, one portion being treated with acetone, which dissolved the heavier constituents without impairing the lubricating value of the oil, and the other was tested in its normal condition. The results of the tests demonstrated that the "treated" oil was an efficacious lubricant and that it burned without producing either smoke or irritating odors. The normal oil, on the other hand, burned, emitted considerable volumes of smoke and an odor described as "highly irritating to the nose and eyes." The tests suggest that methods in vogue to abate the smoke nuisance are perhaps directed wrongly, and that chemical rather than mechanical means might better be employed.

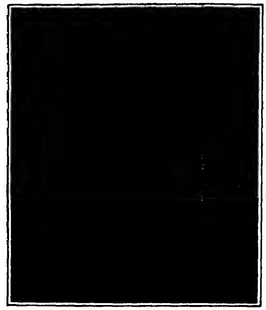
Finding the protein present in grain by the Kjeldahl method.

Soil Analysis and Seed Selection

A New Problem in Agriculture

By L. V. Redman
Department of Industrial Chemistry of the University of Kansas

The chemist in agriculture is concerned with two main problems. The first deals with the composition of the soil and the availability for plant life of its constituents. The second has to do with the selection of seed according to its chemical composition with the object in view of obtaining, not a greater number of bushels of grain per acre, but a greater yield per acre of any one chemical constituent contained in the grain. This latter problem, the application of the law of natural selection to the increase in yield of any one chemical compound present in grain, is new and inviting.—EDITOR.



An hydraulic hand press of 100,000 pounds for expressing oils, waxes, etc.

NITROGEN, phosphorus, potash and lime are the four "critical" constituents which every soil must contain if it is to be productive and a chemical analysis reveals their presence or absence. A good soil to be termed rich must contain at least 0.4 per cent of soluble potash, 0.25 per cent of phosphoric acid, 1.0 per cent soluble lime and 0.25 per cent of soluble nitrogen compounds. The other chemical elements which make up the bulk of all soils are generally present in large proportions, and considerable variation in the amount of these elements present is not critical. An analysis reveals the constituents of the soil and the amount of each element present, but does not always give in a satisfactory manner the availability for plant food of the four critical elements. The reason for this lies in the fact that it is almost impossible to imitate faithfully the solvent action in the plant cell. No solvent has been discovered which will duplicate the conditions found in the growing cell of a plant. Dilute citric acid is the best single solvent for the purpose, although dilute hydrochloric and nitric acids are largely used by the chemists in this country.

When the chemist has determined the constituents present in any soil he must further determine their availability. The constituent potash will serve to illustrate further the meaning of "availability." If potash is present in the soil as a constituent of the rock feldspar it is "locked up" or not available, for the feldspar is practically insoluble. However, if the soil be treated with land plaster or gypsum, the potash is changed into the sulphate of potash and is readily soluble and available for plant food.

And although a chemical analysis is not as comprehensive as one could wish for, yet sufficient valuable practical data can always be obtained by the chemist to repay the cost of the analysis many times over.

Influencing the Composition of Seed by Natural Selection.

A chemical problem which bids fair to outclass others in importance is the selection for sowing of seed according to its chemical composition. The law of natural selection which is being applied with wonderful success to the improvement of races of domestic animals, and also to the gross yield per acre in grain production may be applied with equal success to the problem of producing grain which has a more desirable composition chemically than the existing varieties.

To illustrate this point further all grain is composed of three classes of chemical compounds, fats or oils, proteins and carbohydrates (carbohydrates are sugars and starches). The oils, fats, sugars and starches supply heat and muscular energy to the body. The proteins build up the muscles and nervous tissue, and all mental processes are concerned directly with the breaking down of protein in some form. Proteins are the building materials of muscles and tissues, and the fuel of the brain and nerves, just as fats and carbohydrates are the materials for heat supply to the body. Any grain therefore which can be produced which will contain larger percentages of proteins than the existing varieties will serve two purposes. It will have a larger muscle-building value and nerve value, and its heating properties will be reduced. This is of considerable importance when one recollects that most grains, such as wheat and oats used in the form of bread or as a regular cereal are at least fifty per cent too low in protein for the best support of the individual. The fat and heat producing factors are consequently fifty per cent too high. In corn alone the protein is one hundred per cent too low. Consequently, all cereal diets must be supplemented with meats which are very largely protein. If the protein content can be increased one hundred to two hundred per cent in grains, cereals could safely supplant a large part of our meat diets.

With these facts in mind it is evident that any research work which will increase the percentage of protein per bushel of grain will be of great value.

Some pioneer work in this direction has already been done by chemists. For example at the Government Agricultural Experiment Station in the University of Illinois, there has been developed four distinct "strains" of corn, all from the same original seed. The first strain has forty per cent more protein than the original grain. The second strain has twenty-five per cent less protein than the original. The third strain contains sixty-five per cent more oil than the parent corn, and the fourth contains fifty-five per cent less oil. These changes have been accomplished by ten years of selection based upon chemical analysis.

What changes may be brought about in ten more years or half a century of selection is impossible to predict. A much needed improvement in the muscle and nerve value of our ordinary grains may be hoped for, and a corresponding increase in muscle and nerve energy in the life supported on these cereals.

Atmospheric Ozone Up to Date

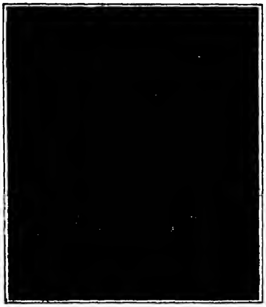
ARTIFICIALLY generated ozone has attained a prominent position in technology, and is daily being put to new uses. What of natural ozone that which occurs spontaneously in the atmosphere? Half a century ago this substance was regarded as nature's great scavenger. Then, and for many years thereafter it was a commonplace that an abundance of ozone in the air betokened a healthful climate. "Ozone" was a word to conjure with and figured conspicuously in the advertisements of health resorts. The air of forests, of mountains, of the sea, was supposed to owe its bracing effects to this gas. The degree of ozonization of the air was tested by the rate of change of some easily oxidized substance, especially the ozone papers devised by Schönbein and variously modified by subsequent authorities.

A deplorable amount of care and labor has been wasted on ozonometric observations according to the traditional methods, which are still kept up by certain meteorologists and hygienists. It has long been known that the so-called ozone reaction indicated by the coloration of test papers, is due partly and perhaps entirely to other oxidizing agents in the atmosphere, such as the oxides of nitrogen, hydrogen peroxide and chlorine. Moreover no allowance is generally made for the varying strength of the wind (with corresponding variations in the amount of air passing over the test papers), the hygroscopic action of the papers, and various other sources of error.

Chemists have made quantitative determinations of the ozone present in a given volume of air with remarkably discordant results. In reference books it is commonly stated, on the authority of Houzeau, that country air, 6 feet above the ground, contains on an average 1/700,000 ozone by volume. This amount would be perceptible to the olfactories, and Houzeau's estimate supports the popular belief that "ozone-bearing air" can be detected by its smell. On the contrary, Ilosvay (*Bull. Soc. Chim. de Paris*, 1889) was unable to find any certain evidence of the presence of either ozone or hydrogen peroxide in the air, but found on the other hand that all the so-called observations of ozone with test paper probably relate to nitrous acid. More recently, Hayhurst and Pring (*Trans. Chem. Soc.*, 1910) made a great number of tests at various altitudes, with the aid of kites and balloons, and found that in every case the amount of ozone was too small to be detected, i. e., less than 1 part in 4,000,000,000 parts of air, up to 8,000 feet above the ground, while at greater altitudes, up to 10 miles, the amount increased but still remained very small.

Ozone is produced in the lower atmosphere by lightning discharges and possibly by other agencies, but probably enters immediately into chemical union with oxidizable substances and therefore has but a momentary existence. The old idea that it is more or less permanently present in regions of the atmosphere inhabited by man and that its fluctuations are of hygienic importance is hardly tenable at the present day.

Nevertheless ozone exists in the atmosphere and is beginning to be looked upon as a meteorological element of great significance. It is formed from oxygen by electrical discharges and by the action of ultra violet light, and most actively when the gas is dry and cold. It is therefore reasonable to suppose that it occurs most abundantly in the upper atmosphere, miles above the earth, where the amount of ultra violet radiation from the sun is much greater than in the lower air, where there are frequent discharges of electricity in the form of the aurora, moisture is almost *nil*, and the temperature is very low. The solar spectrum always shows strong ozone absorption bands, proving that somewhere in the atmosphere ozone is permanently present. The blue color of the sky may be due partly to ozone. However, probably the most important function of the so-called "ozone blanket" of the upper air is its selective absorption in the thermal part of the spectrum, in virtue of which it lets solar radiation in much more readily than it lets terrestrial radiation out. (See SCIENTIFIC AMERICAN, August 6th, 1910, p. 107.)



Weighing large samples in chemical soil analysis.

Increasing the Food Supply of a Nation

How Intensive Farming is Practised in Germany

By Homer C. Price, Dean of the College of Agriculture, Ohio State University

A NATION'S food supply may be increased either by increasing the area cultivated or by increasing the yield per acre. In America we have been using the former method, and in Germany the latter method has been used. Within twenty years the cultivated area of grains in Germany has not increased over 5 per cent, but within this time the total product has increased over 60 per cent, due to the increased yield per acre. This increase has been due to the application of science to the practice of agriculture and has resulted from a better cultivation and handling of the soil, from the more abundant and intelligent use of stable manures and commercial fertilizers and from the selection and breeding of more productive varieties of crops.

A comparison of yields between single years is of little value because one year the crop may be abnormal due to an unusual season, but by taking an average for a period of years a representative yield is given that is a safe basis for comparison. In taking the government statistics of Germany and making a comparison between the average yields for the ten years from 1883 to 1892 and for the five years from 1906 to 1910 they show that the following increases in crop yields have been secured by the German farmers within twenty years:

INCREASE IN YIELD IN FARM CROPS OF GERMANY IN TWENTY YEARS

	Average Yield Per Acre		
	Period 1886-1895	Period 1906-1910	Increase in
Crop	bushels	bushels	20 years
Wheat	21.2	31.2	47.8%
Rye	16.5	28.1	70.0%
Oats	34.1	57.5	68.6%
Barley	24.5	37.2	51.8%
Potatoes	130.0	210.1	61.6%

Practically the same figures for the United States present a very different picture. Our yields are not only in most cases less than one half what they are in Germany, but the percentage of increase has been very much less as shown by the following table:

INCREASE IN YIELD IN FARM CROPS OF UNITED STATES IN EIGHTEEN YEARS

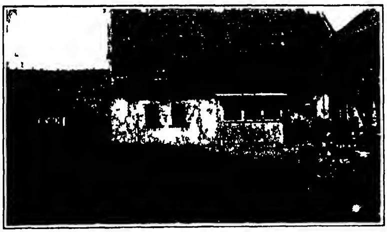
	Average Yield Per Acre		
	Period 1886-1895	Period 1906-1910	Increase in
Crop	bushels	bushels	18 years
Wheat	12.7	14.7	15.7%
Rye	12.7	16.4	29.2%
Oats	25.6	29.0	13.3%
Barley	22.6	24.6	8.8%
Potatoes	74.2	96.9	32.1%

While the yield of wheat per acre in Germany has increased 47.8 per cent in twenty years, in the United States it has increased only 15.7 per cent, notwithstanding the fact that the yield in Germany is over twice as great as in America. A comparison of the tables will show that what is true of the wheat crop is true of the other crop yields. The German farmer is not only producing much more on the same area, but he is increasing his yield much more rapidly than the American farmer. And yet the German farmer has not reached his limit by any means, and one of the leading German agricultural authorities, Prof. Wohltmann, said recently that he was confident the German farmers could increase their present yields 40 per cent within the next twenty years. However this may be, it can at least be pointed out that the German crop yields are constantly increasing from year to year, and as yet there is no tendency to go back or even stand still.

What has made this rapid increase and why are the yields so much greater than in America? is the question that naturally arises. Primarily it is due to more intensive systems of farming, and certainly not to land that is naturally more fertile than in America. The German farmer spends much more labor and capital in the growing of his crops than the American farmer.

Harvesting the kind of crops that make Germany independent

A typical German harvesting scene



Courtyard of a German farmhouse

Center of operations on a German farm

His fields are prepared so that they look like a garden and the soil is in fine condition before the crop is planted. He is more careful in the selection of his seed and his stand of the crop on the ground is more perfect. He has also learned how to feed his crops with fertilizers. In the first place he scrupulously saves every bit of waste on the farm and returns it to the land. Stable manures are carefully preserved and then generously supplemented with commercial fertilizers. The German farmer has learned how to use commercial fertilizers, and he knows they are not to be used to replace stable manures but only to supplement them. He has also learned the necessity of keeping his land filled with humus to make it crumbly so that it is easy to cultivate and will hold rain water that falls on it. He does this by growing alfalfa and legumes, by plowing under green crops and by the use of stable manures.

But back of all this are two causes that are fundamental. First, the active and effective work that the German government has done to develop agriculture. The European nations shape their policies on a war footing and the standard of efficiency sought is to be able to produce their own food supply in case of war. England long ago staked her security in her navy and sacrificed her agriculture to manufacturing and commerce and gave up as hopeless the producing of her own food supply.

Germany together with the other continental nations has maintained high protective tariffs on agricultural products and accepted it as a fundamental problem of national existence to produce in so far as possible her own food supply.

As a consequence an excellent system of agricultural education has been developed and an extensive system of scientific research through agricultural experiment stations is maintained. The governments of both individual States and the general government make generous appropriations for the development of agriculture, all looking toward the one goal—feeding the nation. Chambers of agriculture have been established in the separate provinces and are wielding a tremendous influence in the agriculture of the country. They not only look after the ordinary administrative affairs such as the enforcement of inspection laws, but they are actively engaged in promoting the business interests of farmers through the organizing of co-operative societies, distributing the immigrant labor and every agency that promises to advance the interest of agriculture.

The second fundamental cause of the rapid development of German agriculture has been the efficient business organizations that the farmers have perfected along co-operative lines. This is particularly true in regard to credit. Intensive farming cannot be developed without an abundant expenditure of working capital, and before the American farmer can increase his yields per acre to anything near what the German farmer has done he must have capital that can be secured much more easily and at a much lower rate of interest than is the case at the present time.

German farmers through their land mortgage associations are carrying at the present time over one billion dollars in farm loans and they do not pay over 4 per cent interest for any of it and in many cases not over 3 per cent. There are also over 16,000 rural banks in Germany that are co-operative farmers' organizations owned and operated by the farmers and having deposits of $-,500,000,000. Through these institutions the farmers secure loans for working capital on as favorable terms as is secured by any industrial class. The length of time for which the loan is made and the terms of repayment are adjusted to meet the requirements of agriculture, and in this way the German farmer has a great advantage over the American who almost invariably does his business on too little working capital.

The pessimist who predicts the rapidly approaching time when the farmers of the United States will not be able to produce enough for our own needs, overlooks the possibility of increasing the production from our present area as Germany has done. There is no reason why America cannot do equally as well if

not better He also overlooks the possibility of adding to our present area by reclaiming our waste lands. The United States Geological Survey estimates there are 100,000 square miles of swamp land in the United States that can be reclaimed by drainage, and in the reclaiming of the arid lands by irrigation we have made but a beginning The population of the United States may continue to increase for generations at its present rate and American farmers will be able to produce our own food supply if we foster and provide for our agriculture as do the leading European nations.

The Rise of Agricultural Meteorology

HOW much does unfavorable weather cost the farmer? To what extent is the loss from this cause preventable? Is it not time that meteorologists, plant physiologists and practical husbandmen joined forces in an effort to find out more about the relations between weather and crops?

We cannot alter the weather - the opinion of Sunday Supplement vagarists to the contrary notwithstanding. We cannot temper the wind to the shorn lamb, but—may not the shearing be circumstanced to fit the wind? A thousand acts in our daily life represent so many ways in which we adjust our affairs to the immutable laws of nature The secret of mitigating the loss which weather - and climate which is weather in the aggregate inflicts upon the crops is *adjustment of the plant to its atmospheric environment* This may be accomplished especially in two ways first by the selection of varieties best fitted to the climate, and, second, by planting at such a time that the successive epochs of the plant's life will be most likely to coincide with suitable conditions of temperature, moisture and the like It is true that unseasonable weather will sometimes occur and defeat our best laid plans but in the long run the farmer who times his operations to agree with the normal march of the seasons in his locality will other things being equal, get the most out of his land However, before such a plan can be put into effect we must find out a great deal more than is now known about the meteorological requirements of every species and variety of domesticated plant This is the task of the agricultural meteorologist Meanwhile his colleague the physical meteorologist must aid the cause by carrying out detailed climatic surveys of agricultural lands. Intensive climatology is still in its infancy, and conventional climatic statistics are of comparatively little value to the agriculturist because they ignore local features.

There are many indications that agricultural meteorology is at last coming into its own A notable conference on this subject was held at the last meeting of the British Association for the Advancement of Science An International Commission on Agricultural Meteorology recently appointed by the International Meteorological Committee, held its first session in Paris last September Most important of all the International Meteorological Committee itself, which embraces in its membership the directors of the principal national weather services of the world, will hold a conference on agricultural meteorology at its triennial meeting in Rome next April The International Institute of Agriculture with headquarters in Rome is deeply interested in this subject and has recently published a report showing just what the existing meteorological services *of the world are doing for agriculture* With the recent agitation of the subject centers in the Old World it has spread to our own country and only a few weeks ago the Chief of the United States Weather Bureau assembled a number of his lieutenants at Atlanta to consider what steps should be taken for promoting closer relations between that Bureau and the agricultural colleges and experiment stations

Of all the investigations hitherto undertaken in the scientific borderland between meteorology and agriculture the most grandiose are those now being carried on by the Russian government under the direction of Prof P I Bronnov About 150 stations, scattered over the empire have been specially equipped for such investigations. Each station comprises small plots of land on which a certain succession of crops is grown year after year and meteorological instruments are installed in immediate proximity thereto, in order that strictly parallel observations may be made upon the crops and the weather The most important fact revealed by these experiments is the existence of certain critical periods in the life-history of each plant when the character of the weather markedly affects the yield In other words, the total amount of heat, sunshine rain and so forth received by the plant during the whole period of growth are much less important than the occurrence of definite amounts at certain times. In this respect each species and each variety has its special requirements and up to the present only the principal staples have been studied in detail Already however Russian farmers have become impressed with the expediency of consulting Prof. Bronnov and his staff about the choice of crops and the best time to plant

The farmer lives by the weather, and it behooves him to know as much about it as science can teach him It is passing strange that there are many agricultural colleges at which no course is offered in meteorology Strangest of all—while there are many excellent treatises on marine meteorology, and medical meteorology, and even aeronautical meteorology, an adequate work on agricultural meteorology has yet to be written.

"Myriawatt" a New Unit of Power

THERE is no difference in the measure of power whether produced electrically or by steam, by wind or by water There is absolutely no reason for holding to the old unit 'horse-power,' based on the power of an impossibly strong horse, when we have the "watt" based on the rational centimeter-gramme-second system, merely because the former is commonly associated with mechanical power and the latter with electrical power Logically the name of Watt should be more closely associated with steam than with electricity The term horse-power is falling into disuse among electrical engineers. It is so much easier to rate the power of an engine which drives a generator in terms of kilowatts. In fact, with direct connected engines and generators, it is very difficult to separate the mechanical energy from the electrical energy

But before the engineer can rid himself entirely of the old arbitrary units, there is still to be abolished a unit that *is even more senseless than horse-power for* the reason that the name is practically the same, and yet the value is entirely different. Ever since 1876, when the unit was adopted at the Centennial Exposition, boilers have been rated in boiler horse-power It is defined as the capacity for evaporating 30 pounds of water from 100 deg Fahr temperature of feed water to steam of 70 pounds gage pressure When this unit and the common horse-power unit are both reduced to the common standard of the British thermal unit, we find that the boiler horse-power is thirteen times that of the common horse-power Clearly then boiler horse-power is a misleading term and has no real reason for existing In an effort to get rid of 'horse-power' entirely a paper was recently presented to the American Institute of Electrical Engineers by H D Stott and Haylett O'Neill suggesting that the term 'myriawatt" be used instead The term is derived from the Greek "myria," meaning ten thousand and the term "watt' One boiler horse-power very nearly equals ten kilowatts or ten thousand watts Hence 'myriawatt In terms of British thermal units, one kilowatt is equal to 3,415 units per hour and one boiler horse-power to 33,475 units per hour A 'myriawatt' would then be 34,150 British thermal units per hour or only two per cent more than the boiler horse-power It is the common practice to rate water tube boilers at one boiler horse power per ten square feet of heating surface As this is an arbitrary measure, no harm can be done by increasing the unit two per cent, and boilers might hereafter be rated at one 'myriawatt" per ten square feet of heating surface.

At a joint meeting of the Standard Committee of the American Institute of Electrical Engineers, and a special committee appointed by the American Society of Mechanical Engineers, the new term was recommended and Mr C O Mailloux was appointed to present this unit to the International Electro-Technical Commission at Zürich It seems quite probable that the term will be adopted abroad, where 'boiler horse-power' is never used, and no suitable substitute exists.

The new term permits the use of a simple system of determining the over all efficiency of a plant. For it is only necessary to divide the kilowatt output by the myriawatt and multiply by ten to obtain the per cent of efficiency The input of a plant and its output need no longer be stated in different and unrelated units of power All power can be measured in terms of a single unit. Blessed is the man who makes one word grow where two words grew before

Teisserenc de Bort (1855–1913)

AMERICAN meteorologists thought of the late Léon Teisserenc de Bort as "the French Rotch," and of the late A. Lawrence Rotch as "the American Teisserenc de Bort" Both men enjoyed ample private fortunes and were generous patrons of meteorology; each of them built and directed a private meteorological observatory, and each was the great pioneer aerologist of his country This parallel has unhappily been completed by the death of both in middle life, and within a few months of each other

Teisserenc de Bort was born in Paris, November 5th, 1855. From 1878 to 1892 he held an active position, and from the latter year onward an honorary position, on the staff of the Central Meteorological Bureau of France. In 1896 he founded his observatory of dynamical meteorology at Trappes, not far from Paris, and here he began about 1898 the series of sounding-balloon ascensions which led to the astonishing discovery of the isothermal layer of the atmosphere—first formally announced to the French Academy of Sciences in 1902. Twentieth century meteorology may be said to date from this achievement, as nineteenth century meteorology did from the discovery of the law of storms.

Even had he not discovered the isothermal layer—which he subsequently renamed the "stratosphere"—Teisserenc de Bort would rank with the greatest meteorologists. His idea of "centers of action" in the atmosphere is pregnant of practical and theoretical results not yet fully realized. He was one of the foremost advocates of the world wide outlook in meteorology and the founder of the plan of collecting daily meteorological reports by telegraph from stations all over the globe now being elaborated by an international commission, of which he was president. His charts of high level isobars, and his discovery of the relations between anomalies of temperature and pressure, marked definite advances in our knowledge of the atmosphere. He was one of the creators of the international classification of clouds. He joined with Rotch in fitting out the expedition, on the yacht "Otaria," which established the existence of the antitrade winds above the northeast trades.

In company with H. H Hildebrandsson he began some years ago the publication of a great historical work on dynamical meteorology, unhappily not yet completed. In 1908 he received the Symons gold medal of the Royal Meteorological Society, which is awarded every two years "for distinguished work in connection with meteorological science. He was recently elected a member of the Academy of Sciences.

The Growth of Stumps

IT occasionally happens, particularly with trees growing in wet or very moist soils, that stumps of the Cuban pine (*Pinus heterophylla*) and long leaf pine (*Pinus palustris*) continue to grow by laying on very narrow annual rings of woody tissue for a number of years after the trees have been felled The stumps of Douglas fir (*Pseudotsuga taxifolia*) and redwood (*Sequoia gigantea*) likewise continue to grow in diameter for a longer or shorter period of time It was observed some time ago in Florida that a good many stumps of Cuban and long leaf pines felled more than ten years previous had continued to form annually new layers of growth These annual rings are very narrow, often only from three to six cells wide, and are indistinctly visible even under the high power of the microscope

What appears to puzzle the forester most of all is how the roots retain their vitality for such a long time and supply the cambium of the stump and larger roots with a sufficient amount of manufactured food to deposit layers of wood Before the food material can be utilized by the tree it must be manufactured in the leaves. A chestnut tree, for instance, produces new shoots from the root collar as soon as it is felled and the leaves on these young shoots supply the root system with elaborated food. The stump thus continues to live, but the pines do not ordinarily produce stump shoots and can not manufacture food material for themselves. It would seem reasonable to conclude, therefore, that the roots of these pines are parasitic and are grafted on those of the neighboring trees, which supply the pine stumps with the required amount of prepared food The roots of closely allied species of trees often unite, especially in shallow wet soil, where the roots of both young and old trees are near the surface and necessarily come in close contact with one another

The irregularity with which the wood is often deposited clearly indicates that the roots of only one side of the stump have joined those of the living trees. Sometimes the fresh wood deposited on one side is more than double that on the opposite side This new wood produced is often scarcely distinguishable from that formed naturally The fibers or tracheids are usually interlaced and in an isolated state are curved and have blunt ends. The markings on the cell walls are similar to those of normally formed tissue. The compound microscope reveals the fact that the cell walls are slightly thinner and that there is little or no distinction between the early and late wood in these narrow zones.

Holland Gas Exposition

THE gas exposition of Amsterdam, which closed October 13th, 1912, numbered among its exhibitors 200 firms of different countries, only one of which was from the United States. It contained some interesting exhibits, such as the model of a Utrecht factory for making gas from petroleum residue by a process of dry distillation. This invention is considered of especial importance to the United States on account of our large production of petroleum. Other exhibits included a safety gas meter having automatic devices for preventing asphyxiation from escaping gas, an electrical gas lighter having a lighting switch against the wall, and a burner and mantle which can be used with either end up.

Effect of Reservoirs on Freshets

To the Editor of the SCIENTIFIC AMERICAN

Mr H R. Flint's article on the control of the Mississippi, in your January 11th number, contains an important fallacy which should not be passed unchallenged Mr Fl nt pretends that the existence of reservoirs, even those of "many square miles in extent," does not regulate or equalize the flow, for the reason that "the extra water that causes the flood comes on top of reservoirs already filled" by previous rains. In this assumption, however, he is quite mistaken, even if it were not true that the level of reservoirs in all modern constructions can be and is regulated according to requirements. The rate of flow over the spillway of a dam varies with the square of the head, or level of water in the reservoir above the edge of the spillway, and this head will of course, for a given quantity of water flowing into the reservoir, vary inversely as the reservoir's area. This is a fact of such common observation, even aside from any mathematical consideration, that no demonstration should be required Water powers on streams are rendered useful in proportion to the storage capacity of the reservoirs back of them The immense value of Niagara's power consists largely, if not mostly, in the greatest power reservoir in the world which lies back of it.

Of course, the existence of a reservoir must "lower the ultimate high-water mark attained by the stream" by just the amount of water added to the reservoir, and inversely as the time it takes to run out.

This is not in any sense analogous to the influence of a forested watershed on stream flow, as Mr Flint assumes, because when the ground is saturated, the "reservoir" is filled to capacity and no longer stores any water

Milwaukee, Wis. GEORGE W COLLES

The Alaska Reindeer Industry

To the Editor of the SCIENTIFIC AMERICAN

I have just noticed in the issue of January 4th the letter of Mr A. W Williams, of Chena, Alaska, regarding the Alaskan reindeer herds, which, in view of the wide circulation of the SCIENTIFIC AMERICAN, I consider worthy of notice.

Mr Williams implies that the Bureau of Education's reindeer enterprise in Alaska is unsuccessful in that it does not provide a draft animal and a meat producer throughout all of the vast and varied regions of Alaska.

Mr Williams has entirely misconceived the object of the Bureau of Education in this undertaking It is neither the duty nor the endeavor of the Bureau of Education to furnish Alaska generally with a draft animal and a meat producer Its Alaska reindeer industry is confined solely to the native population of Alaska, its object is to provide assured means of support for the natives of the vast untimbered grazing lands of northern and western Alaska, which are adapted for reindeer raising in this it has been eminently successful.

Instead of being "confined entirely to narrow strips of land bordering the oceans," the reindeer industry affects a region approximating in length the distance from Maine to South Carolina. In this region reindeer herds are found in the valleys of the Noatak, Kobuk, Selawik, Yukon, Kuskokwim, and other rivers, at many points hundreds of miles from the coast. The northernmost herd is near Point Barrow, on the shore of the Arctic Ocean, in latitude 71 degrees 27 minutes, longitude 156 degrees 20 minutes, the southernmost herd is at Ugashik, in southwestern Alaska, forty miles from the North Pacific Ocean, in latitude 57 degrees 50 minutes, longitude 154 degrees 50 minutes. A straight line from Point Barrow to Ugash k is approximately 960 miles in length A line connecting each of the fifty-three herds would be more than 5,000 miles in length

The official reports for the fiscal year ended June 30th, 1912, show a total of 38,307 reindeer in Alaska, of which 624 natives own 24,003, or 62 per cent, representing at an average value of $25 a capital of $600,075. The total income of the natives from the reindeer industry during the fiscal year, exclusive of value of meat and hides used by the natives themselves, was $44,885.04.

Mr. Williams's statement that my natives (I was the superintendent to whom he referred) "had to shovel snow several hours in order to enable the reindeer to reach their food," and that the Government had required "the continued services of between thirty and forty men to shovel snow off the moss" or the Holy Cross herd, is without foundation. No men were employed to shovel snow and, so far as I know, none was shoveled. On the trip to which he has referred, I used reindeer as draft animals all winter, covering a trailless country from Unalakleet to Cold Bay, via Kuskokwim, Nushagak, and Iliamna, traveling a distance of more than 2,200 miles—a record to compare favorably with that of the best dog teams in Alaska, when cost, comfort, and condition of trails are taken into consideration I neither broke trails on snow shoes, nor pushed behind handle bars—I rode

What is Mentality?

To the Editor of the SCIENTIFIC AMERICAN

In recent years I have had more or less to do with feeble-minded people, and have come to a new realization of how much mentality depends on physical organization This experience has materially modified theories previously held as to the genesis of the individual mind

My present theory is this Mentality, thought, consciousness, whatever you will, is the expression of the reactions that occur between nervous (electro-chemical?) energy and energy generated in the blood stream The brain alone is usually spoken of as the organ of mind, but the brain in itself is as powerless to produce mental action as a dynamo to produce electricity without conjunction with some external force This external force in the case of the brain is the energy produced by the blood All brain action ceases at once if the blood supply is shut off, and the individual drops into the blank of extinction

A long array of facts, inexplicable by the brain theory, are reasonably explained on this hypothesis of brain and blood interaction The normal mind arises from normal blood and brain When either of these is abnormal, or both abnormal, the resulting reaction is abnormal and we have the abnormal mind

The animal body is a wonderful chemical laboratory, and the blood it manufactures is composed of many chemical elements contributed by the numerous glands and other tissues Now if any of these glands and tissues are defective or absent, so that the elements they furnish are defective or missing, the blood is thereby made defective and a defective mentality results If a person has a diseased thyroid gland, or if it is missing, we have the cretin, a feeble-minded person If this gland has such decided influence on the quality of mind may it not fairly be assumed that other glands have a similar influence? Indeed, we know they have The gelding has neither the robust mentality nor the robust physical constitution of the entire animal

In all the past and up to the present, mankind has been unable to discover the real nature of insanity, epilepsy, feeble-mindedness, because they have looked for the cause in the brain alone or in the nervous system, or in the secretions alone the secret lies probably in the reactions indicated and these have been and are still beyond detection.

Everything that comes into existence does so through some process In a universe where everything is inexplicable in its ultimate to the human understanding is this hypothesis as to the genesis of the individual mind unreasonable? Henri Bergson says "From this ocean of life in which we are immersed, we are continually drawing something and we feel that our being, or at least the intellect that guides it, has been formed therein by a kind of local concentration" Supposing that there is an ocean of life or an ocean of mind still there must be an individual process to generate the individual life or mind, there must be this "local concentration" as Bergson terms it, and why should not the interaction of blood and brain energy be the process, seeing that both are necessary to life and mind?

Of course individual, conscious immortality is destroyed by this hypothesis, for when the complex of forces is dissolved out of which the individual arises, body and mind, the personality is forever dissolved

Perhaps this theory is not new, but so far as I am concerned it is If a similar one has been advanced by anyone, I have not seen it It it can be shown to be untenable, well and good It is the truth, so far as we are able to comprehend the truth, that we want.

Fairibault, Minn EDGAR ODSON

The Fallacy of the Spring Wheel

To the Editor of the SCIENTIFIC AMERICAN

For purposes of comparison, assume that a vehicle is equipped with full elliptical springs between the body and the axle and that the wheel is a "perfect spring wheel" When a load is imposed upon the vehicle, the elliptical spring and the bottom and top spring of the wheel will be depressed This depression we may call the normal depression. If the wheel is to have the same shock-absorbing efficiency as the elliptical spring, then the normal depression of both must be approximately equal. In the case of the wheel springs, however, it is clear that the springs below the hub of the wheel and the springs above the hub are flexed in opposite directions, so that in one revolution of the wheel the springs in it must undergo a flexure of double the normal depression Therefore, if the vehicle were driven over a perfectly level road, the elliptical spring would simply remain in its position of normal depression while the springs in the wheel would sustain a flexure of double the amount of the normal depression at every revolution The spring of a 40-inch wheel would therefore sustain approximately 525 double normal flexures in every mile in addition to the flexures caused by the absorption of irregularities of the road

The working of the springs due to the irregularities of the road will be the same in either case Now, if we represent the amount of this working per mile by X, the normal depression by Y, and the miles by M, we can represent the comparative working of the two springs as follows

Work in elliptical spring, MX

Work in spring wheel, $M(X + 1{,}050\ Y)$

The springs in the wheel must therefore undergo 1,050 complete normal flexures in each mile more than the elliptical springs. This would develop an amount of heat and a rate of depreciation in the spring wheel which, in the opinion of the writer, makes it practically certain that no spring wheel, however ingenious and perfect in action, will ever become a practical success

This same reason is recognized, even by the layman, as the cause for the rapid depreciation in automobile tires, but so far as the writer is aware, has never been recognized in connection with the spring wheel

Plainfield, N J G F FISHER.

Panama Canal and Free Tolls to Domestic American Shipping

To the Editor of the SCIENTIFIC AMERICAN

The note of Earl Grey to the Government of the United States in protest of the free tolls to American domestic shipping using the canal in trade between United States ports, made the point that if American shipping did not pay tolls, there would be no means of ascertaining the additional burden that would be laid on foreign tonnage

That would hardly seem to enter into the case, at least not for many years, as Prof Emery Johnson pointed out in his report to the United States Government that the United States would have to make up the deficiency in the canal revenue for years to come, even though American ships all paid tolls

So as far as foreign tonnage is concerned, the United States allows foreign tonnage to use the canal at less than cost

Free tolls for American domestic shipping is indefensible from every and any standpoint It is in effect a subsidy to as great a monopoly as exists on the sea—American coastwise tonnage

American coastwise tonnage is shielded from the competition of any foreign steamers None but American-built craft can engage in the trade between the United States Atlantic-Pacific ports

To give this tonnage free tolls is the same as handing it money from the United States treasury, and no thought whatever is given to the interests of shippers No thought apparently is given as to the possible combination that may be effected by the owners of American coastwise tonnage that will engage in the trade

And from the present reports of the activity in shipyards the world over, including the United States it would not be a surprising thing to find that in the course of a year or two, it would be a difficult matter to place an order for tonnage and secure anything like prompt delivery, freights meanwhile being at the mercy of tonnage owners that have no more hesitation in charging all the traffic will bear than have railroads

And besides this, there is a phase of the matter that so far has apparently not been touched American steamers engaged in trade to foreign ports and using the Panama canal will have to pay tolls While American steamers engaged in domestic coastwise trade using the canal will go through free

On what grounds can Congress make such a distinction? It is class legislation pure and simple, discrimination of the worst sort, taxing American steamers engaged in foreign trade and exempting them in domestic

No one has ever claimed that we would have to extend aid to tonnage to uphuild our coastwise trade The efforts that have been made in Congress in the last decade have been in behalf of American tonnage that was to upbuild our deep-sea foreign trade American tonnage on the deep seas "could not stand the competition of foreign steamers" "It cost more to operate the American, cost more to build and compete it was necessary that Congress extend aid in the shape of bounty or subsidy," and Congress turned a deaf ear to that part of the American merchant marine that did make a somewhat plausible showing, that needed aid, and later grants a measure of subsidy—for that is what free tolls is in effect—to that part of the American merchant marine that not alone needs no subsidy of any kind but which is and has been favored as has the shipping of no other nation

In the interest of American fair play the free toll measure should be recalled, that would be one justifiable act And not alone in the cause of justice should it be, but on the ground of discrimination there is nothing in the Constitution or in law that permits Congress to levy tolls on American shipping using the canal and destined for ports outside of the United States, and giving free passage to American ships destined to ports of the United States.

Economics of the Farm Tractor

The New Way of Tilling the Soil and What it Means

By Philip S Rose

SINCE the very dawn of time agriculture has depended upon the muscular power of men and animals to perform all of its heavy work Even after all of the other great industries had adopted steam or gas or electricity, agriculture continued to plod along in the time honored custom, because forsooth nothing else was available This condition continued until very recent times. About a dozen years ago the steam tractor was developed sufficiently to attract the attention of many of the large western grain farmers and then, less than ten years ago the gas tractor using gasoline or low grade kerosene for fuel, made its first appearance From that time forward the pace has been rapid.

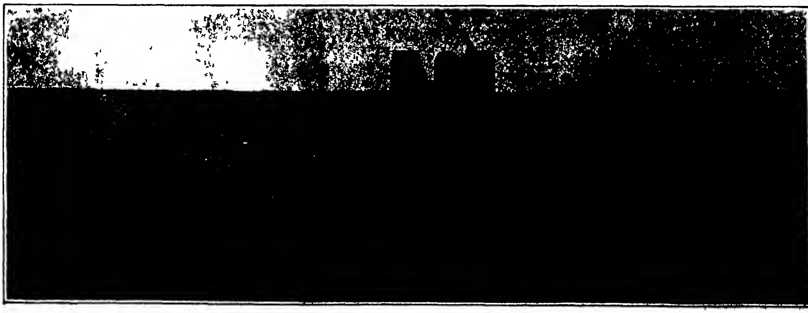
Farmers everywhere are now talking about power farming and thousands have become converts to the new idea Six years ago there were not to exceed five hundred gas tractors in the United States Last year more than thirteen thousand were sold, and this year the factories of the United States will turn out no fewer than twenty thousand Five thousand of these will be sold in western Canada Of the remaining fifteen thousand some will go to South America, some to Russia and some to the various countries of Europe but the greater number will be sold to the farmers of the United States

Next year more than twenty thousand will be made and sold The demand is greater than the supply and continues to increase from year to year There are now more than eighty companies engaged in their manufacture, and new ones are being formed almost weekly Such is the condition of the business, and its prospects for the future seem very bright indeed It looks as though the commercial success of the automobile were to be repeated in the farm power field

All this activity is easy to understand when one comes to consider the immense expenditure for power necessary to conduct the agricultural operations of the country The total cultivated area of the United States is 477,488,000 acres, of which a little more than 43,000,000 is annually devoted to the hay crop, thus leaving about 435,000,000 acres that must be plowed and made ready for the crop each year It is estimated that the average work necessary to plow an acre is about ten horse-power hours. At the Winnipeg Motor Contest last year the average of all trials showed that it required 15.41 horse-power hours to plow an acre, so the figure selected appears to be on the safe side. Using this as our power factor, we find that the total expenditure of power for plowing the ground once each year is 4,350,000,000 horse-power hours. In order to accomplish this task and do the other necessary work, which amounts to more than twice as much additional, there were on January 1st of the past year, according to the report of the Secretary of Agriculture, 24,002,882 horses and mules on the farms of the United States. Their total value, as given by the same source, was estimated at $2,698,351,000. The average value per head is thus $112.53, which is certainly low enough These animals are maintained almost exclusively for farm power use, and do not include those used in cities and villages. If we take into account the harnesses and other gear required before this power is available, estimated at fifteen dollars per animal, it is evident that the farmers have the prodigious sum of three billion dollars invested in power equipment.

If we assume in round numbers 480,000,000 acres as the total cultivated area, and three billion dollars as the investment, a

Billows of earth left in the wake of a tractor plow.



Majestically a huge tractor moves through acre after acre, drawing in its train a dozen agricultural implements.

little calculation will show that the farmers of this country have an average of $6.25 an acre invested in animal power. This sum seems excessive, but as a matter of fact it is greatly exceeded by many farmers. The truth of the figures becomes apparent when one considers that they provide only two work animals to each forty acres of cultivated land. Besides, the estimated value per animal is very low. There are hundreds of farms where the cost per acre is greatly in excess of the figure given.

Authorities differ as to the annual cost of keeping a horse. Grisdale, of the Ottawa Experimental Farms, reports an annual cost of $99.80 for each of the nineteen horses at the station farm. Burkett, of the New Hampshire Station, reports the average cost of keeping five horses at $74.38 each, while Cooper in Minnesota found the farm cost of keeping horses to vary from a minimum of $65.23 to $90.40. If we assume an average cost for the entire country of $75 per head, which seems reasonable in view of the above figures, we find the total cost of maintenance of this important industry reaches the enormous sum of $1,805,400,150 or $3.76 per acre.

The total value of all agricultural products for the year 1911, as estimated by the census, is $8,417,000,000, which amounts to $17.53 per acre for the entire United States. From this it will be seen that it requires 21.4 per cent of the products of the farms to maintain their work animals. In other words, more than one hundred million acres are required to raise food and pay for the maintenance of the horses and mules of the United States. Truly this is an enormous tax upon our national resources and at a time, too, when the production of human food is not keeping pace with our increasing population. Is it any wonder that farmers are looking toward mechanical power with eager hopefulness? These animals do not furnish food or clothing directly and hence their total cost must be chargeable to the annual national farm power bill. In this discussion, it should be especially noted that we have omitted all interest and depreciation charges. If these were taken into account we should have to add about sixty two cents more to the maintenance charge per acre, which would bring the total up to $4.38, or almost exactly twenty five per cent of the country's agricultural production annually.

While perhaps few farmers have ever kept an accurate account of the cost of keeping their work animals, they are nevertheless, aware that they are paying an enormous price for the power needed to do their work. Not only are they paying a heavy price for the power itself, but the fact that it is divided up into such small units makes it necessary to employ many extra laborers during the busy season. The change to mechanical power operates in agriculture just as the adoption of improved machinery in manufacturing. It reduces the number of men required to perform a certain piece of work, and thus reduces the cost.

Owing to the nature of farm work and the fact that there is a long idle period during the year, it is difficult to maintain enough laborers in the country to do the work during the busy season. This fact, coupled with the high maintenance cost of work animals, has turned the minds of farmers toward mechanical power. They figure that they can well afford to buy a tractor instead of keeping a dozen or more horses. The tractor does not require special attention during the times it is idle. It does not cost anything for fuel while idle. It does not require as many operators as the horses it replaces, and it is able to turn out more work in a day. Moreover, it is able to work longer hours and during the hottest weather. The speed with which it can prepare a field for a crop or seed the ground after it is prepared is an important item, for it is well known that the yield often depends upon the soil condition when the ground was plowed or the moisture content of the soil when the seed was planted. A rapid machine like a tractor enables the farmer to take advantage of soil and climatic conditions much more successfully than when he depends upon horses.

It is true that the tractor is not adapted to the small farmer. It costs too much. Prices now range from $1,200 to $3,000. The higher price is for the larger machines which will develop anywhere from fifty to eighty horse-power.

These machines can easily do as much as twenty-five or thirty horses, while the smaller machines, which will develop from fifteen to forty horse-power, are fully equal to ten or a dozen horses. The first cost of the larger machines is not much if any greater than of the horses which they replace while the cost of the smaller machines is not greatly in excess.

It is the general opinion of well informed tractor men that it will pay any farmer who has two hundred or more acres under cultivation if his land lies right, to purchase a gas tractor. For a farm of that size he will need one of the smaller machines. His power bill for the year should then figure about as follows:

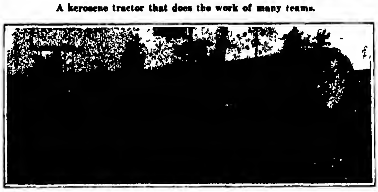
Interest at 6 per cent	$72
Depreciation	200
Fuel, oil and labor	160
Total	$532

At the average of $4.38 for all horse labor the total would have amounted to $876. These figures show a gain of $344 for the tractor.

Any set of estimates are liable to be misleading. Much depends upon the character of the farm where mechanical power is contemplated as to whether it will pay to make the change or not. The kind of farming and the mechanical ability of the farm owner or manager are the items that must come in for careful consideration. Perhaps the best way to approach the subject, and thus arrive at the fact, is to consider the experiences of those who have used gas tractors.

Pulling binders by engine power

A kerosene tractor that does the work of many teams.



Hauling logs in Tennessee over roads that are roads only in name

There is no place in this country where power farming is carried on more extensively than around Beach, N. D. and Wibaux, Montana. The farms are large and horses are used merely for driving purposes and to haul light loads from town if the farmer does not possess an automobile. All the heavy work such as plowing, disking, seeding, threshing and hauling the crop to market is done with tractors. Many steam tractors are used, but gas tractors are the favorite.

As an example of the amount of work a tractor can do in a season, take the record of E. G. Paul, one of the Beach tractor farmers. Last year he plowed 810 acres of sod, disked 800 acres, seeded 1,600 acres, harvested 1,440 acres and threshed and then hauled his grain to market besides doing a considerable amount of road grading. E. A. Beasley, a prominent farmer near Lake City, Iowa, says he finds his tractor more economical and satisfactory than horses. Joe Edgington, another Iowa farmer, reports that it cost him less than eighteen cents an acre to do his plowing last fall with an engine burning distillate. He used two and three quarter gallons an acre, which cost him six cents a gallon.

The most of Montana has been developed with mechanical power, and the three western provinces of Canada depend upon it. It would seem if these Canadian farmers can make power farming pay that the farmers of the United States would certainly find it profitable. In order to obtain some idea of the costs of operation and to obtain an expression of opinion regarding the efficiency of the tractor I sent out a list of questions to forty four Canadian farmers, asking the cost of fuel, cost of outfit, labor charges, repairs, etc. and finally asking for an expression of opinion in regard to the future of the gas tractor. Eleven replies were received and every one expressed the opinion that the gas tractor would soon displace every other kind of power in Canada. This, too, in face of the fact that tractors cost twenty five per cent more than in the United States, and fuel fully twice as much. Several reported using gasoline that cost twenty-seven cents per gallon and yet they were enthusiastic for the gas tractor.

The work reported as being done by tractors covers a wide range and includes all field operations, such as plowing, seeding, harvesting, hauling to market, threshing, corn shredding, grinding, baling hay, filling ditches, and road grading.

There is no question but we have entered upon a new era in agriculture. The farmer desires the comforts and advantages of the city dweller and these he gets easily and cheaply with the small gasoline engine. He sees that the gas tractor is suitable for the heavier field operations and is generally more economical than horses, and he is not slow to make the change. It enables him to accomplish more in a season. It multiplies his capacity and gives him either more leisure or enables him to farm a larger area and increases his income.

Power farming has just begun, and the start is encouraging. Whether it will accomplish the revolution in agriculture that it has in manufacturing and transportation only time can decide, but it seems safe to predict that it will bring about many interesting social and economic changes.

X-ray Pictures of Micro-organisms

By Dr. Alfred Gradenwitz

THE latest advance in the field of radiography is the use of X rays for examining microscopic preparations.

If in spite of the many sided applications of X rays, no attempt had so far been made to use them for microscopic study, this was doubtless due to the serious experimental difficulties to be overcome. A French scientist, M. Pierre Goby, at Grasse, has however, by means of a special apparatus (particulars of which will only be made known in a short time) succeeded in removing these difficulties and investigating opaque microscopic preparations by radioscopy in all their most hidden details.

As pointed out in a memoir recently submitted to the French Association for the Advancement of Science, Goby at first placed his micro-radiographic work in the services of paleontology and conchyliology. The most primitive organisms (protozoa) all kinds of foraminifera and similar microscopic beings can thus be investigated in their innermost structure. Goby has even succeeded in ascertaining the existence of differences in species when ordinary methods of investigation only showed the existence of a single species.

It is known that sea sand contains fossil remains of all sorts of microscopic organisms. When examining a sample of such sand under the microscopic X ray apparatus, a surprising abundance and variety of forms is revealed, each individual being analyzed far more safely than under the microscope. In addition to these applications, micro radiography also lends itself for investigating the formation of the bones of small vertebrates from their birth to the adult stage. Apart from the structure of bones, peculiarities of the skin and any anomalies of small, though not microscopically small animals can be investigated with the utmost care, any fleshy parts and even muscles becoming transparent so as to come out distinctly on the background. Studies in comparative anatomy are thus greatly facilitated.

Other applications will doubtless be found in the near future, those above mentioned would seem to give an adequate idea of the possibilities of this new science, the further development of which will be left to the experimenters themselves.

The Library of the Late Prof. Skeat has been presented to King's College, London, where, with the library of the late Prof. Furnivall, presented to the same college, it is to form a departmental library of the School of English Language and Literature.

The Heavens in February

How Astronomical Predictions Have Been Verified in the Laboratory

By Henry Norris Russell, Ph D.

PROBABLY the most remarkable feat of astronomical spectroscopy has been its discovery (by its spectral lines in the light of the solar atmosphere) of the rare gas helium long before this element had been run to earth in our laboratories. A similar story hardly less remarkable has just come to its final chapter by the production in the laboratory of a set of lines in the hydrogen spectrum, long ago known to exist in the stars

In some ways this tale is even more remarkable than that of helium It is easy enough to understand that when astronomers find in the spectrum of the Sun's chromosphere a number of lines that cannot be reproduced from any known substance, under any known method of treatment they may legitimately assume these lines to be due to some unknown gas, and call it helium from the place of its presumed occurrence

But in the case now under discussion a number of spectral lines never observed (till many years later) in the laboratory have been confidently assigned to hydrogen one of the most familiar of substances, and, what is more the positions of other lines of hydrogen never observed in the stars, and incapable of observation there, have been predicted and after fifteen years these assumptions and predictions have been triumphantly verified by experiment

To understand how these truly extraordinary things have been done, we must consider for a little the fascinating subject of series of lines in spectra

In the spectra of many elements, there exist sets of lines, sometimes single often double or triple which show a regular spacing, the successive pairs lying nearer to one another and becoming fainter toward the violet end of the spectrum When the number of lines in the spectrum is great it is often difficult to pick out such series if they exist but in spectra showing relatively few lines, the series are often the most conspicuous features.

Perhaps the finest of all examples of such a series is the great system of hydrogen lines which are so conspicuous in the spectra of the white stars (like Sirius) and appear also with less intensity in the solar spectrum The same lines may be produced without difficulty, by passing an electric discharge through hydrogen contained at low pressure in a vacuum tube As long ago as 1885 Balmer showed that the wave-lengths of these lines (which define their position in the spectrum) could be calculated with great exactness by the formula

$$\lambda = 3646.13\,\frac{m^2}{m^2-4}$$

in which $m = 3$ gives the wave-length of the red line (called C in the solar spectrum) $m = 4$, that of the blue F line, etc. The remaining lines lie in the violet and ultra violet parts of the spectrum, and lie closer and closer together crowding toward a definite limit. Only about eight of them can be photographed in the spectrum of the vacuum tube, but in the stars and the solar chromosphere, where conditions seem to be in some way more favorable many more can be seen. In fact, all the lines of the series as far as $m = 31$ have been measured on Evershed's eclipse photographs, and the agreement of the observed and calculated wave-lengths is practically perfect.

Study of other elements showed the existence of similar but somewhat more complicated series. The alkali metals—sodium potassium, etc—show in their spectra *three* series of pairs of lines. The numerical formulae for calculating their positions become simpler if we take not the *lengths* of the light waves, but the *number* of waves in a given distance say a centimeter When this is done it is found that the interval between the lines of a pair measured in this way is exactly the same for all the pairs belonging to two of the three series while the third series is composed of pairs which grow rapidly closer as the lines lie farther to the violet

The first two series of lines have the same limit, toward which the successive pairs converge, while the limit of the third series is usually far in the ultra violet This last series contains the strongest lines in the whole spectrum and is consequently called the "principal series" The other two "subordinate series" of fainter lines may be distinguished from one another by the fact that the lines of one series are usually sharp, and those of the other usually diffuse when examined under high dispersion. These sharp and diffuse series are so arranged that the pairs of one sort and the other alternate in the spectrum, presenting a very beautiful picture, which can be seen by any one who can look, with a spectroscope of very moderate power at an electric-arc whose carbons are plentifully treated with some salt of sodium.

It will not do, however, to use a Bunsen burner, for, at the relatively low temperature of its flame, only the lines of the principal series of sodium are visible, and but one pair of these—the familiar lines in the yellow—lie within the visible spectrum It is not until the atoms of the metallic vapor are exposed to the more violent disturbances, thermal and electrical, which befall them in the electric arc that they begin to vibrate in the ways, and at the rates, which give rise to the lines of the subordinate series.

Very interesting numerical expressions for the wave-lengths of the lines of such series have been given by Rydberg, who uses equations of the form

$$\frac{1}{\lambda} = n_0 - \frac{N}{(m+\mu)^2}$$

in which m has the values 2, 3, 4, etc., n_0 and μ are constants, different for each series of lines, and N is a "fundamental constant," which is the same for all series and all elements, and must depend on some universal peculiarity of atomic structure.

The constant μ is usually not a whole number, but is less than unity If we make it exactly unity, and give n a proper value, the formula reduces to that for the "balance series" of hydrogen.

When the equations for the different series are written in this way a remarkable connection appears between the "principal" and "sharp" series. In fact, the equations for the two may be combined in the formula

$$\frac{1}{\lambda} = \frac{N}{(m_1+\mu_1)^2} - \frac{N}{(m_2+\mu_2)^2}$$

(considering for simplicity a series of single lines)

Here μ_1 and μ_2 are two constants. If we keep $m_1 = 1$, and give m_2 the values 1, 2, 3, 4, we get the positions of the lines of the principal series, while if we let $m_2 = 1$, and make $m_1 = 2, 3, 4$, etc., we get (after changing signs) the wave-lengths of the sharp series. It is obvious that if we know the lines of one of these series we can work out the formula, and then calculate where the lines of the other series ought to be.

This relation has been tested on several elements showing such series in their spectra, and found to be generally true (though not perfectly accurate, presumably because the exact formula is a more complicated algebraic expression)

The bearing of all this on hydrogen and astronomy is as follows In 1896 Pickering discovered, on photographs of the spectrum of Zeta Puppis (now visible low in the southern sky) a series of lines in the middle of the intervals between the familiar hydrogen lines, and very like them. On measuring their wave-lengths, he found that they could be very closely represented if, in the well-known formula of Balmer, the values $m = 3\frac{1}{2}$, $4\frac{1}{2}$, $5\frac{1}{2}$, etc., were inserted instead of 3, 4, 5, etc. This was evidence enough to make it very probable that the new lines were really due to hydrogen, whose atoms were stirred up to vibrate (perhaps by very high temperature) in additional ways, besides those already familiar, just as happens to the sodium atoms in passing from the flame to the arc.

Rydberg, after Pickering's measures were published, promptly showed that the positions of the lines could be very accurately represented by a formula of his type The two series of hydrogen lines appeared to be related just like the two "subordinate series" in the spectrum of sodium, etc., the familiar lines corresponding to the "diffuse" and the new to the "sharp" series. It was now possible, using the last formula which is written down above, to predict where the lines of the principal series of hydrogen ought to be, if the previous hypotheses were true.

One of these predicted lines of wave-length 4686 on the usual scale, in the blue, agreed with the uncertainty of the measures with a bright line observed in the spectrum of Zeta Puppis and some other stars, and also in the spectra of some nebulae, and (as was later shown) faintly in the Sun's chromosphere The other predicted lines lay in the extreme ultra violet, with wave-lengths less than half that of the D lines. For light of such short wave-lengths, our atmosphere is very imperfectly transparent. Thicknesses of a few feet, such as come into question in laboratory measurements, exert a moderate absorption, but the miles of air through which the light of the Sun and stars must come are, for these rays, entirely opaque

There was hence no further possibility of testing Rydberg's brilliant hypotheses by astronomical means.

So the matter stood for fifteen years, until Prof Fowler of South Kensington, a very distinguished spectroscopic authority, discovered, only a few months ago, that if a very powerful electric discharge is passed through a mixture of hydrogen and helium, in a vacuum tube, the lines under discussion can be observed. Hydrogen alone has not yet been made to give the new spectra, but from the reasons already given there is no doubt at all that it, and not the associated helium, is responsible for them.

The measured positions of the lines of longer wave-length agree perfectly with those observed in the stars, and the lines of the principal series are there, in just the calculated positions. An additional set of lines, intermediate between those of the principal series, and forming a fourth series, related to it very much as the other two series are related, have also been shown on Prof. Fowler's plates, but all these lines are so far in the ultra violet that they are of no astronomical importance.

It would hardly be possible to find a more beautiful instance of the confirmation of scientific predictions; and all concerned in it—Prof. Pickering, Prof. Rydberg, and Prof. Fowler—may well receive the heartiest congratulations upon the completion of this almost romantic chapter of spectroscopic history.

The Fourth Award of the Scientific American Medal

An Oxygen Fed and Driven Device for Artificial Respiration

THE fourth bestowal of the SCIENTIFIC AMERICAN Medal was made with the usual care by the Jury of Awards of the American Museum of Safety on January 23rd at a largely attended meeting held in the auditorium of the United Engineering Society's building. Before the meeting, at which four medals were awarded, a dinner was served in the Rossiter W. Raymond room, which was attended by ninety distinguished guests, including Dr. and Mrs. Andrew Carnegie, Mrs. Thomas A. Edison, and many other persons well known in humanitarian movements.

President Arthur Williams presided at the meeting. The SCIENTIFIC AMERICAN Medal was awarded to the Draeger Oxygen Apparatus Company of Pittsburgh, Pa., and Lübeck, Germany. The presentation address was made by Dr. Frederick H. Hutton.

In part Prof. Hutton said:

"It is the pleasant and precious privilege of the Museum of Safety to be the representative of the community and of you all in recognizing the splendid quality of altruistic service. It is the dream and inspiration of the Museum, that on some day the trustees may discharge this duty in its own building built and operated by the State, which has delegated its duties to it, and by the municipality which benefits principally by its activities, as well as by the generous co-operation of the individuals who recognize its opportunities. But, at present, we do this pleasant duty in a hall belonging to someone else, and the medals which we award are the gifts of individuals or corporations who have been keen-sighted to see that by endowing such a medal they were fostering and fanning the spirit of uncompensated service for industrial mankind.

"These medals are four in number. They will first be listed and the recipient named, with the reasons for the action taken, and then the delegated representatives will be asked to come to the platform, that the medals may be handed to them in person.

"The medals are listed in chronological order.

"The SCIENTIFIC AMERICAN Gold Medal must be for some safety or life-saving device, invented within a recency of three years, and exhibited in the Museum's collections. The device selected for 1912 in this class is the Pulmotor.

"The phenomena of respiration are combinations of mechanical action and chemical re-actions. The presence of poisons in the blood-current stimulates the brain cells, which automatically start up the muscles of diaphragm and thorax, whereby the chest cavity is expanded and air flows in to react upon the blood exposed to such oxygenating action. If the poison is excessive, if the lung cavity is filled with water, or if the chemical compound in the blood is stable or unbreakable, oxygenation does not take place, the nerve centers are paralyzed and death results. If the nerve centers are paralyzed by excessive electrical action, respiration stops."

We give herewith a description of the Pulmotor in greater detail than was possible in an address.

The Pulmotor, for which the specific award of the SCIENTIFIC AMERICAN Medal was made, is an oxygen-feed device designed primarily to induce respiration by artificial means in persons overcome by noxious gases, electric shock, the apparently drowned, or in any other cases where the breathing of the patient has been seriously impaired or stopped entirely, but where there still remains a slight heart action. The object of the apparatus is to inflate and deflate the lungs in a rhythmic manner, and the pulsations of the mechanism are so timed that about the normal number of respirations per minute is obtained. Its motive power is an oxygen cylinder containing this gas under a pressure of 120 atmospheres, which will supply a 60 per cent mixture of air and oxygen to the patient for forty minutes. Should it then become necessary, the empty cylinder may be replaced with a new one with a loss of but a few seconds. It has the great advantage over artificial respiration by hand in that it forces larger amounts of oxygenated air into the lungs than is possible by the ordinary methods of artificial respiration and it makes it possible, through its automatic mechanical action, to keep up the work for long periods. The Pulmotor is so adjusted that it will force air into the lungs until it reaches a pressure of about 3/10 pounds, so that the same result is thus mechanically obtained as forced breathing in a healthy conscious man; therefore when the three pounds pressure is reached the apparatus reverses mechanically until it obtains a negative pressure of three pounds, so that all of the deoxidized air is thrown out, leaving the lungs empty and free for a new supply. This pressure is particularly valuable in cases of gas poisoning because five atmospheres pressure will maintain oxygen in the blood fluid even after the blood cells have been so damaged by carbon monoxide that they are no longer able to maintain life, but life is maintained by this artificial means until the hemoglobin of the red blood cells which normally carries the oxygen can recover itself.

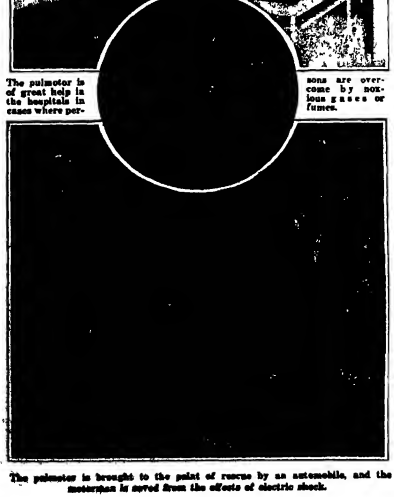
The Pulmotor in its case weighs about fifty pounds, so that it can be carried about readily in automobiles, fire trucks or ambulances. The wooden case contains two entire separate pieces of apparatus, an oxygen inhalation apparatus for ordinary oxygen inhalation (mounted on the lid of the case for use after life has been restored) and the special apparatus for artificial respiration which is housed in the case itself. The two pieces of apparatus have in common the oxygen cylinder and the pressure-reducing valve, and either of them can be set in operation singly by turning a suitably arranged lever to the right or left upon the reducing valve. The steel oxygen cylinder is closed by a valve which can be opened by a turn of the thumb and finger. The cylinder contains 11½ cubic feet of pure oxygen. The oxygen passes from the reducing valve to an injector which has the property of drawing in a large volume of air with a certain force of suction, and propelling that air forward with equal force through the flexible tube in front of the injector. This suction and delivery injector, therefore, serves as a motor, alternately filling the lungs by pressure and emptying them by suction. The most striking part of the Pulmotor is a small leather accordion bellows which effects the automatic reversal of the apparatus from suction to delivery and vice versa when essential. The bellows is connected with the air tubes. During inflation the same pressure obtains in the bellows as in the lungs, and as soon as the latter are filled the bellows becomes inflated and in moving forward causes the valve to be automatically reversed into position for suction. The operation is now reversed, and as soon as the lungs have been emptied the bellows contracts and automatically reverses the valve again into position for inflating—and so on. From what has been stated it will be clear that the respiratory rhythm of the apparatus readily adapts itself automatically to the capacity of the lungs in every case. The rhythm will be slow when the lungs are capacious, and faster with those of smaller dimensions. The apparatus performs all these functions without any assistance from the hands, so that the operator can turn his attention to an important thing, namely, keeping the wind-pipe open and closing the gullet. The essential condition to the success of artificial respiration is the provision of two flexible breathing tubes on the mask. One of these tubes serves exclusively for the supply of pure air and oxygen, while the simple inhalation apparatus can be called into play, and as already stated, this portion of the apparatus is carried on the lid.

Some of the results obtained by the use of the Pulmotor are most remarkable. On February 15th, 1912, several Pulmotors were ordered for installation at as many Byllesby properties. Up to January 1st, 1913, twenty-four lives had been saved by the twenty-three machines, and a number of cases have been reported subse-

(Concluded on page 131.)

The pulmotor in its case ready for use.

The pulmotor is of great help in the hospitals in cases where persons are overcome by noxious gases or fumes.



The pulmotor is brought to the point of rescue by an automobile, and the motorman is saved from the effects of electric shock.

A GROUP OF INTERESTING MACHINES AND ENGINES WHICH SHOWS HOW GASOLINE AND OIL POWER CAN BE MADE TO DO THE FARMER'S WORK.—[For article see next page.]

Gasoline and Oil Power on the Farm

How Engines Have Lightened Farm Work

By Philip S. Rose

THE uses for the gas engine are legion. It is the mechanical chore boy of the farm, the Percy or mechanical man of agriculture. It can be and is used in the house, in the barn, in the field and in the garden. There is hardly any place where there is work for a man to do that the gasoline engine cannot be used to advantage. It can be used in the house to run the washing machine and wringer, to pump water and furnish lights.

Many farmers have a small shop fitted up near the house where they have installed a shop for the repairing of tools, a laundry, an electric lighting plant, a cream separator, and perhaps a churn and other small machinery, all of which is run by a four or five horse-power engine.

An electric generator of two kilowatts capacity, with a storage battery, will light the house, the barn and the grounds, besides furnishing enough current to operate fans, flat irons, a sewing machine and perhaps a mechanical milker.

The cost of current so generated will not exceed ten cents a kilowatt hour, a figure that compares favorably with what the city dweller has to pay to the central station. If the shop can be built around the well, as many of them are, the same engine can also pump the water and deliver it to all parts of the farm buildings. One of these little machines makes it possible for every farm to have all the modern conveniences of the city home and at no greater expense.

Even if the same engine cannot be used to do all this work it costs very little to buy enough small units to take care of the various jobs that need to be provided for. The cost of a gasoline engine ranges from twenty five to thirty five dollars a horse-power whether the engine be large or small, so there is no economy in buying one large engine. It is better to buy several and place them where they will be needed most of the time.

Doing Farm Work with Gasoline

Such engines will run on about a pint of gasoline per horse-power per hour, or with gasoline at sixteen cents a gallon, at a cost for fuel of only two cents a horse power hour. The same amount of work with human labor will cost at least one dollar and twenty cents, for a man will charge at least fifteen cents an hour and can do only one eighth of a horse-power of work. Furthermore, you know when you set an engine at work that it will not loaf on the job and you are getting the full worth of your money.

If the gasoline engine had been invented and brought to its present state of perfection a hundred and fifty years ago we would never have had human slavery in the South. No slave, no matter how hard the task master, was ever able to compete with one of these mechanical men in the amount of work turned out in a day, nor in the cheapness with which such work can be accomplished.

Our teachers of agriculture tell us that if we are to maintain the fertility of our soils and make a permanent success of agriculture we must raise more live stock. To do this we must grind feed, shred corn fodder and put up ensilage. Cattle and hogs and sheep cannot be allowed to pasture on high priced land, they must be kept in the stables and fed. Here then is where the engine of a little larger size can and must be used. Engines of twelve to fifteen horse-power, either stationary or mounted on trucks so that they can be moved easily from place to place, are the ideal size for this heavy work. In addition they can be used to thresh the grain, and many farmers are so using them. There are a number of small separators on the market designed for just this purpose.

The Cost of Filling a Silo with Power

As an example of how efficient a gasoline engine is for filling silos all we need to do is to turn to a bulletin published by the Virginia Experiment Station which gives the report of experiments on the cost of filling silos with different kinds of power. It was shown in these experiments that the cost of filling a silo with gasoline engine power, using gasoline that costs thirteen cents a gallon, amounted to only two to three cents a ton as against two to seven cents a ton for steam engines using coal at five dollars a ton.

Another big field for the gasoline, or to be more exact in the use of terms, for the crude oil engine is in irrigation. Vast areas in Colorado, Texas and Kansas have been reclaimed with the use of such engines which pump from wells sixty, seventy and even eighty feet deep. Thousands of engines of from five to fifty or more horse-power are already in use and the number is daily increasing.

A gentleman who made a thorough study of conditions in the Louisiana rice fields last summer stated that in one parish in Louisiana alone there is an opportunity to replace fifteen hundred steam engines with an equal number of gasoline engines on account of the high price of coal and the difference in efficiency in favor of the gas engine.

Another large field of usefulness for the gas engine, though not directly concerned with agriculture, is in the *cotton gins of the South*. These are rapidly changing to the cheaper power.

In the fruit growing regions every fruit grower needs a gasoline spraying outfit and it requires one such outfit for every ten acres of orchard, because the time when spraying must be done is very limited and a day or two's delay means the saving or losing of a crop worth thousands of dollars.

Even the poultry farmer finds the gasoline engine indispensable for grinding bone and preparing food for his poultry, while market gardeners all through the humid belt circumvent the vagaries of the weather and overcome the handicap of a long drought by the use of some overhead system of irrigation. One manufacturer, who covers the territory east of the Mississippi River has sold thousands of outfits that irrigate tracts up to ten acres or more in extent and prove sources of increased revenue to those forehanded enough to make use of them.

How Many Engines Are Necessary?

Thus it will be seen that every farm, no matter what the product thereof, can find profitable use for gas engine power. The small farm of only an acre or two needs at least one, while the large farms need several. One farmer writes that he has seven gasoline engines and finds them indispensable, while another reports five. A man engaged in mixed farming in Minnesota declares that every farmer on a quarter or a half section farm ought to have at least three engines of two, six and twelve horse power, respectively. This man started out a few years ago with horses and men as his only source of power, and now has adopted gasoline engines everywhere he possibly can. He still uses horses, it is true, but with the small engines about the farm and a tractor in the field he finds it easy and more profitable to dispense with a large number of surplus horses and keep fewer hired men.

As an example of the value of one of these engines for special service, consider the special binder engine, which, mounted on the rear of a binder, operates the sickle and binder head and thus dispenses with two horses. Where the grain is heavy or the ground muddy it requires at least four horses on a grain binder, but with an engine to operate the working parts of the machine, two horses are sufficient. This was discovered a number of years ago in the Red River Valley when a heavy rain came on just when the grain was ready to harvest. The straw was very heavy and the soil so saturated with moisture that the wheels would fill up with mud and refuse to turn. A number of people then resorted to a gasoline engine fitted up on the rear of the binder, and in that way all that was saved that year of the wheat crop of the valley was saved by the aid of gasoline. Since then there has been a growing demand every year for binder engines. Wherever the grain is very heavy the little engine will relieve one team and do the work easier and cheaper. Last year, owing to the heavy straw, these engines were shipped from the factory to the grain fields in carload lots by express.

In parts of the country where there is much tile draining to be done special gas engine driven ditchers are coming into use. Some of these are home-made, some factory made. An example of one of the former type came under the writer's observation not long since in Iowa. It is fitted with a fifteen horse-power gasoline engine and is capable of digging twenty rods of trench a day for 36-inch tile at a fuel cost of only five dollars. There are millions of acres of land in this country that need drainage, and it is such machines as these that will make the work possible. If we had to depend upon human labor to do all the excavating the cost would be well nigh prohibitive, even though tile draining doubles and in some cases trebles the value of the land. One of these machines can easily do as much in a day as fifteen men.

The Experience of Farmers with Gasoline

Instances of the use of gasoline engines could be multiplied almost indefinitely. The experiences of farmers everywhere are the same. Listen to what a few of them have to say in regard to this subject. Here is one from Indiana. He writes: "Three years ago I purchased a two horse-power engine to pump water from a hundred and fifty foot well. In the fall we used it to cut corn fodder, then fitted it up to a wood saw and later to run a small feed grinder. If I were buying another engine I would get a larger one, but I only expected to use this one for pumping until I realized its adaptability and added the other duties."

An Illinois farmer reports as follows: "We have three engines on our farm, one is two and a half horse-power, one six and the other eighteen. The small one is used for pumping water, washing, sawing wood and for all small jobs. I got the six horse engine to run the corn dump and to help out the small engine. Later, I converted it into a tractor to more easily take it to the various jobs I wanted done. It is a success, too. The big engine is used to run a feed mill and has ground thousands of bushels of corn and oats for cattle feeding."

A New York farmer, evidently a poultryman, writes that he uses his seven horse engine to run a pneumatic ensilage cutter, a meat chopper and a bone grinder, while a Nebraska farmer who kept an accurate record of his work writes that he sawed eighty four loads of pole wood, each load averaging three quarters of a cord, in fifteen hours and fifty five minutes and used only four and a half gallons of gasoline.

From all parts of the country come the same reports of adaptability, efficiency and economy. We are only at the beginning of the use of power in agriculture, but its use is spreading with tremendous rapidity. The era of power farming is upon us, and it seems destined to work almost as much of a revolution as did the entrance of mechanical power in manufacturing.

Farmers' Bulletins

THE publications of the U. S. Department of Agriculture during the last fiscal year included 2,110 different bulletins, circulars, reports, and other documents, of which 34,678,557 copies were issued. Of these 10,409,000 were Farmers' Bulletins. The series bearing the latter title represents one of the most remarkable examples extant of the activities of a paternal government. It now includes more than 500 titles, running through an almost exhaustively wide range of subjects of practical interest in connection with rural life and industries. For example, during the past year Farmers' Bulletins were issued on "House Flies," "The Use of Concrete on the Farm," "Forestry in Nature Study," "Tuberculosis," "Ice Houses," "Lawns and Lawn Soils," "The English Sparrow as a Pest," and some forty other topics. The publications of this series are all distributed gratis to the public, either directly by the department or through members of Congress, and although they are printed in large editions (from 20,000 to 250,000) the stock on hand is soon exhausted, and many applicants are disappointed.

The Current Supplement

THE Bureau of Railway Economics recently published a bulletin in which a study is made of the capital values and net returns of Agriculture, Manufacturing Industries, and Railways. The salient points of this important bulletin are presented in an abstract which appears in this week's issue, No. 1935, of the SCIENTIFIC AMERICAN SUPPLEMENT.—Dr. A. Nestler tells us many interesting facts about Plants Venomous to the Touch.—The Berlin correspondent of the SCIENTIFIC AMERICAN reports on recent work in "high frequency" moving pictures, in which no less than one hundred thousand photographs are made per second, showing the movement of a pistol lock, and the discharge of the empty cartridge.—Davis H. Tuck makes some interesting comments on the census of power production in the United States during 1912.—A number of industries, such as the manufacture of soaps and candles, make use of hard fats, as distinguished from oils, i. e., liquid fats. To these industries a process for converting liquid into solid fats is most valuable. Such a process is described in an article translated for our readers from a German source.—The capital of British India has by imperial act been transferred from Calcutta to Delhi. Some of the engineering and sanitary problems involved in the construction of the new city are discussed by Sir Bradford Leslie in an article illustrated with fine examples of Indian architectural art, the beauty of which may surprise those who have not made themselves familiar with these matters.—The function of micro-organisms of the soil in agriculture is lucidly discussed by G. W. Moses.

RECENTLY PATENTED INVENTIONS

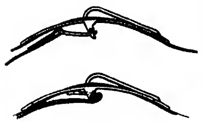
These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

GARMENT HANGER.—L. KALINA, care of Midget Mfg. Co., 178 Center St., New York, N. Y. This invention provides a hanger for supporting coats, vests, suits, trousers, skirts, shirt waists and other garments, and is adapted to be folded into a comparatively small space for convenient carrying in a vest pocket or stowing it in a traveling bag or other similar traveling article.

NECKSCARF.—T. DEWEY and F. J. DEWEY, Plattsburg, N. Y. This invention is intended more particularly for embodiment in four-in-hand and like scarfs in the form of a continuous band or strip of a length to constitute a neck band, and to be formed into a knot, leaving depending flaps or ends.

BUCKLE.—W. J. FRINK, 11 E. 4th St., Chattanooga, Tenn. The invention has for its object the provision of a holding device for a buckle especially designed for ladies belts, which can be attached to delicate fabrics with-

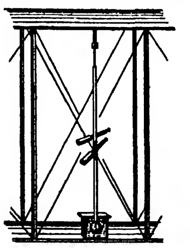


BUCKLE.

out injuring them, without requiring the use of stitches, rivets, pins, or the like and without regard to the thickness of the fabric. The device may be easily attached and detached.

Pertaining to Aviation.

SPEED FINDER FOR MOVING BODIES.—C. S. STANWORTH, 111 Warren Crescent, Norfolk, Va. To facilitate observation by means of this invention fixed lines of sight are laid off at definite angles from a vertical bar and the observer has only to note the elapsed time of the passage of the object across the two lines of sight, and by reference to a table the



SPEED FINDER FOR MOVING BODIES.

speed can be calculated, and the point at which it is necessary to release a projectile or mailbag so that it will strike within a given area can be determined. The principal advantage of the finder is that the lines of sight are fixed angles, and no manipulation of measuring instruments are required. A fragment of an aeroplane is illustrated herewith, showing applied thereto a speed finder.

AEROMOTOR BOAT.—S. S. JEEWAN and F. S. JEEWAN, 21 Convent Ave., New York, N. Y. The invention is an aeroplane having a motor boat attachment so that the aeroplane can alight upon a body of water and propel itself over the surface thereof or be caused to rise from the surface of the water and resume its flight whenever the operator desires.

AEROPLANE.—A. J. A. DEPERDUSSIN, 9 Rue des Entrepreneurs, Paris, France. This invention uses a controlling wheel mounted upon a pivoted bow or bridge of inverted U shape, which spans the width of the fuselage, the ends of the arms of the bow being pivoted at two fixed points on either side of the fuselage, one of the arms of the bridge carrying the cables operating the altitude rudder. Such arrangement permits utilization of the rigidity of the main frames to resist the pull of the cables while the bridge allows room for the pilot's legs. Also, the cables are separated the whole width of the frame, it is therefore convenient to connect them to the ends of the long horizontal arms of the three-arm lever placed upon the landing frame and having a short third arm attached to the operating cables which pass toward the planes over two pulleys located substantially at the same height as the end of the short arm.

Electrical Devices.

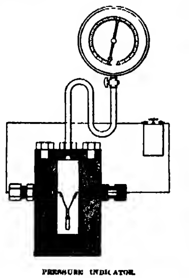
SYSTEM OF ELECTRICAL SUPPLY.—W. C. WOODLANDS, care of Packard Electric Co., Warren, Ohio. The principal object here is to provide a series lighting circuit which is inductively controlled, the system being arranged so that the load may be altered the power factor remaining substantially constant. The system is inductively controlled through the medium of a suitable transformer together with reactances in the primary and secondary transformer circuits.

ELECTRIC SWITCH.—C. E. KNOWLTON, 212 W. 3rd St., Rochester, Minn. The switch shown in the accompanying drawing is of the button type, the buttons being arranged

ELECTRIC SWITCH.

to tilt on suitable journals so as to close or open the double knife switch. The switch is noiseless, and when the current is on the lower half of the button projects from the wall plate. To open the switch the button is tilted back flush with the plate.

PRESSURE INDICATOR.—J. H. WILSON, 15th St. and Center St., Ashland, Pa. This invention is more particularly directed to a device especially adapted for testing the explosive pressure of detonators or blasting caps. The principal object is to provide a testing



PRESSURE INDICATOR.

device whereby the explosive pressure in pounds exerted by a blasting cap or electric detonator will be directly indicated. It provides a testing device of substantial construction whereby the force exerted when a blasting cap or electric detonator explodes may be indicated directly on a pressure gage. The engraving shows in section the operative relation of the device, together with a blasting cap or a detonator suitably held in position therein and in circuit with a battery.

Of Interest to Farmers.

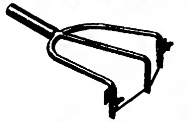
MOWING MACHINE.—A. J. ANDERSON, 22 Greenwich St., New York, N. Y. This machine is self-propelled and is provided with new and useful means for controlling the cutter bar

MOWING MACHINE.

frame. The principal object is to provide a machine having a plurality of bars thereon, the frame carrying the bars being more or less loosely constructed whereby these bars may adapt themselves to unevenness in the ground when the machine is in use. A further object is to provide means for removing the cutter bar driving mechanism out of operative position in order to permit the machine to be run over the ground with the bars inoperative. The illustration herewith represents the machine in a side view.

AUTOMATIC MILK CAN FILLER.—J. W. MULLER, care of G. L. Thacker, Chehalis, Wash. The invention provides a means for filling milk cans, bottles, etc., in succession the milk flowing into the first of a series of cans, and when the first is filled the milk is automatically shut off from this filled can and permitted to flow into the next can of the series, and so on successively to the end of the series of cans.

GARDEN RAKE.—JAMES DICKSON, Box 813, Goderich, Ontario, Can. The principal object of the invention illustrated herewith is to provide an implement adapted to receive



GARDEN RAKE.

a temporary device to shatter or agitate the ground through which it is drawn. This is effected by connecting the tines of the rake with a wire which as the rake is pulled through the ground serves to loosen the earth surrounding plants.

MAPLE SAP EVAPORATOR.—G. H. SOULE, Fairfield, Vt. In this invention use is made of a heater, a pan adjacent to the heater and having a tortuous passage extending from one side at the rear to the front and back to the rear at the other side, inlet connections connecting the heater with the pan at both sides and at the rear of the pan, means for closing either connection and syrup outlets on the pan adjacent to the inlets.

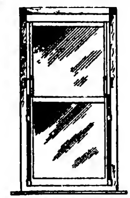
Of General Interest.

SPOOL HOLDER.—M. E. CHESSEY, care of Sanford Novelty Company, Sanford, Maine. A spoolholder is provided in the present invention which may be conveniently attached to the garment of the person and which provides not only a receptacle for a spool, but a

SPOOL HOLDER.

delivery guide for the thread drawn from the spool and receptacle. The device is of compact form and may be readily kept in a work basket when out of service.

WINDOW.—R. B. HARTSFIELD, 210 W. 114th St., New York, N. Y. This invention relates to windows having stiles mounted to slide up and down, and sashes pivoted on the said stiles to admit of turning the sashes on the stiles. The purpose is to provide a window arranged to permit of conveniently turning the sashes with a view to allow cleaning of

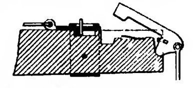


WINDOW.

the outer faces of the sashes from the inside of the room. For this, use is made of a window frame having parting strips of fixed and movable sections and cross-bars carrying the sections and mounted to swing on the sides of the window frame to allow of turning the sashes on their stiles at the time the movable sections and their cross bars are swung into the outermost position. The engraving shows an inner face view of the window.

BOOK LINE GUIDE RULER.—C. E. GOULDING, 1015 S. Dakota Ave., Tampa, Fla. This invention provides a ruler adapted for adjustment of disalined and separate book sections, provides an operating mechanism for rulers to enable them to be adjusted to a margin, provides rulers to hold in adjusted position the open sections of books and to show the continuous line across the two half faces thereof.

HORSE RELEASING DEVICE.—R. E. CHANTRY, Big Arm, Mont. The object is a releasing device with clips to which the tug straps may be secured, the clips being disposed in recesses in the back of the swingletree having forwardly extending shoulders disposed in bearing openings in the swingletree



HORSE RELEASING DEVICE.

and lateral arms disposed in the slots on the swingletree so that the locking slides provided for engaging the back of the clips will hold the clips in position on the rear of the swingletree until the locking slides are drawn back, when the clips will pivot on their shoulders, and the inner ends of the clips be thrown free from the swingletrees. The engraving shows an enlarged sectional view of the end of one of the swingletrees, with the locking slide drawn back to free the clip.

ANTISEPTIC PROTECTOR FOR MOUTHPIECES.—F. A. DIETERICH, 910 Caldwell Ave., Bronx, N. Y., N. Y. The inventor provides a protector for the mouthpieces of telephones, speaking tubes and the like and arranges to present to the user a thoroughly disinfected and agreeably smelling traveling web extending over the entrance end of the mouthpiece with a view to prevent contamination of the mouthpiece and to protect the user against transmittable diseases.

TRUSS.—F. DASSORI, 1115 84th St., Brooklyn, N. Y. This invention is designed for the relief of sufferers of hernia and is so constructed that it will hold any rupture no matter how old, obstinate or recalcitrant under all conditions, and without causing any inconvenience to the wearer.

DAM.—C. BLAW, 505 Pittsburgh Bank of Savings, Pittsburgh, Pa. The object here is to provide a dam preferably constructed of concrete or other suitable material which will possess the maximum amount of strength, rigidity and stability with the least amount of material. A further object is to provide a structure in which the side thrust is resolved into a component, bringing the strain downward.

TRUSS.—F. PUELAN, Apartado 261, Guadalajara, Jal., Mexico. The pads of this truss are mounted on a bar which forms the lower part of a right frame secured to the body by a preferably flexible strap. The frame is so formed that one side thereof projects in a

TRUSS FOR HERNIA.

direction at right angles to the general direction of the bar on which the hernia retaining pads are mounted and is arranged so that the right angle portion will accommodate an abdominal pad which acting against the belt will give a leverage action for properly holding the hernia supporting pads to their work. A perspective view of the device as applied to an abdominal rupture is shown in the accompanying illustration.

REVOLVING CARD STAND.—J. A. MANSON, 347 W. 87th St., New York, N. Y. The object here is to provide a revolving stand so constructed that the display cards may be readily dismounted and replaced. Another object is to provide a stand more particularly adapted to carry display cards such as is described in full in Mr. Manson's copending application Serial No. 661,079, filed November 20th, 1911.

Hardware and Tools.

COMBINATION LOCK.—D. KATZENBERGER, 215 W. Huron St., Chicago, Ill. In this con-

struction the combination can be easily and readily altered without access within the lock case and further it prevents the engagement of the pin or finger with the disk tumblers from being detected in the working of the knob also it provides for the positive actuation of the lock bolt in both directions

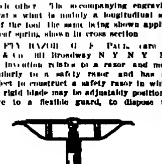
LIFTER.—C E Ballow Los Angeles, Cal The principal object of the inventor is the provision of a cylinder lifter having means thereon for rotatably mounting it in position whereby the device is capable of manual operation thereby being adapted for use in places where such an outfit is desirable but where power is unavailable

TOOL FOR USE IN OILING LEAF SPRINGS.—H Hutchinson care of Elmer H Lineman Syracuse Neb In this invention the improvement is a tool for use in separating the leaves of elliptic or semi-elliptic carriage springs sufficiently to permit the introduction of oil or other lubricant between them

TOOL FOR OILING LEAF SPRINGS

for the purpose of relieving friction between the leaves and enabling them to slide easily on each other The accompanying engraving illustrates what is mainly a longitudinal section of the tool the same being shown applied to a leaf spring, shown in cross section

SAFETY RAZOR.—G F Paul care of Munn & Co 361 Broadway N Y N Y Mr Paul's invention relates to a razor and more particularly to a safety razor and has for an object to construct a safety razor in which a thin rigid blade may be adjustably positioned relative to a flexible guard, to dispose the



SAFETY RAZOR.

blade at different distances from the guard according to the requirements of the user The engraving herewith shows a side elevation of the invention the upper position being cut away centrally to represent certain portions in section and showing the position of the parts before the blade is clamped into position

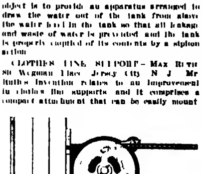
Heating and Lighting

STOVE.—G T Ouseley 3411 S Washington St Frankfort Ind This stove provides for the continuous flow therethrough of air from the room which is to be heated It provides means for causing the soot to be deposited at the top of the stove instead of being carried into the pipe and in such a way that the soot so deposited will be burnt up and destroyed when the stove is in use

Household Utilities.

SIPHON FLUSHING APPARATUS.—J J Meyer 100 Lenox Ave Yonkers, N Y This invention pertains to flushing tanks for water closets urinals and other fixtures and its object is to provide an apparatus arranged to draw the water out of the tank from above the water level in the tank so that all leakage and waste of water is prevented and the tank is properly emptied of its contents by a siphon action

CLOTHES LINE SUPPORT.—Max Ruth 86 Wegman Place Jersey City N J Mr Ruth's invention relates to an improvement in clothes line supports and it comprises a compact attachment that can be easily mount



CLOTHES LINE SUPPORT

ed upon the side of a house adjacent a window thereof and by means of which the clothes line can be readily and conveniently operated to enable the wash to be hung out to be dried and taken in after drying.

Machines and Mechanical Devices.

AUTOMATIC SAW SHARPENING MACHINE.—E. S. Bussy Putnamville, Vt. This machine is designed more especially for grinding sharpening or gumming the teeth of straight or circular saws, and arranged to allow running the machine at a high speed, to quickly sharpen the saw to insure positive intermittent feeding of the saw and positive movement of the grinding wheel to and from the saw and to reduce vibration to a minimum and thus permit accurate and uniform sharpening of the teeth of a saw

HAT FLANGING MACHINE.—T J MacDonald 131 Nepperhan Ave Brooklyn N Y This machine is arranged to enable the operator to reach every part of the brim with a view to facilitate the setting and flanging thereof For this operation the hat block is mounted to turn on the carrier adapted to be swung from a horizontal into an upright position or vice versa

CABLE FOR THE TRANSMISSION OF MECHANICAL MOVEMENTS.—Nicolas Hemsmark 7 Rue de Poliveau Paris, France The purpose here is to provide a flexible cable for the transmission of mechanical movements of all kinds capable of acting by traction without stretching and by contraction without becoming shortened It consists broadly of a core constituted by one or more wires contained in the interior of a tubular helicoidal winding with contiguous spirals, the core being in permanent tension between two stops which bear at each extremity of the cable upon the winding

Prime Movers and Their Accessories.

PACKING.—G R. Waight dec'd W A Kruger executor 16 Newberry St Providence R I The object of this invention is to provide a packing more especially designed for use on piston rods, valve stems and the like and arranged to allow convenient adjustment with a view to take up wear For this purpose use is made of a tubular packing made in sections and encircling the rod or stem the sections being provided with conical ends and rings having conical openings engaging the conical ends by holding the sections together and pressing the same against the rod or stem

Railways and Their Accessories.

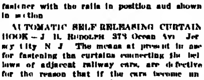
RAIL FASTENING.—S. B Kill, 150 E 45th St Manhattan N Y The aim here is to provide a rail fastening arranged to securely hold the rail in place and to prevent spreading of the same Use is made of converging spikes, of which one is the rail spike and engages the rail and the other is the locking spike and engages the rail spike to lock the latter against displacement

RAILROAD TIE AND RAIL FASTENER.—F C Seaman 3 Academy Place Oneonta N Y The inventor provides improvements whereby the ties are rendered practically indestructible and the rails are securely held in place to prevent them from spreading The tie is made in the form of a skeleton metal casing and a concrete filling and the tie is provided

RAILROAD TIE AND RAIL FASTENER.

with recesses for the reception of rail supporting blocks for the rails to rest upon and rail clamps bolted to the sides of each of the said rail supporting blocks and engaging the corresponding rail at the opposite sides thereof The illustration is a side view of the tie and fastener with the rails in position and shown in section

AUTOMATIC SELF RELEASING CURTAIN HOOK.—J H. Rudolph 378 Ocean Ave Jersey City N J The means at present in use for fastening the curtains connecting the bellows of adjacent railway cars, are defective for the reason that if the cars become uncoupled unless care is taken to disconnect the curtain the parting of the cars will tear or rip the same from their fastenings. The invention provides a fastening hook at the free



AUTOMATIC SELF-RELEASING CURTAIN HOOK

edge of the curtain to firmly hold the same under normal conditions, but which will automatically permit the release of the curtain when a strong pull is exerted on the latter The edge rod of the curtain may be readily inserted and the several parts of the device may be locked to change the same from an automatically releasing hook to a locked hook. The illustration shows the bolt and jaws in protracted position showing the curtain rod.

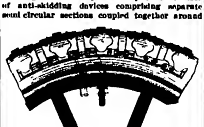
FEED WATER HEATER FOR LOCOMOTIVE BOILERS.—A. Dunnett and C Didier, Santiago de Chile, Chile. The invention consists of a cylindrical feed-water heater for locomotives, which heater is disposed in the smoke-box directly above the passage for the exhaust steam from the cylinders, and is provided with a number of vertical tubes through which the exhaust steam is made to pass. On the top this heater is provided with a concentric conical hood for collecting the exhaust steam, which hood has a mouth piece serving as a blast pipe

CAR DOOR SECURING MEANS.—T H Abernethy Box 172, Shelby, N C. The invention pertains to a car door securing means and more particularly is directed to an improvement whereby the said means when released may serve the purposes of a lever to assist in opening or closing the door

OPERATING DEVICE FOR STATION INDICATORS.—W B Hill, Hotel Seneca San Francisco, Cal The invention is an improved form of a station indicator previously patented by the same inventor A drum is driven from a revolving part of the running gear, and the drum and novel co-acting manually-controlled elements are designed to increase the efficiency and precision of operation and to simplify the adjustment and control

Pertaining to Vehicles.

ANTI SKIDDING DEVICE FOR TIRES.—I D. Meals 306 Cumberland St Harrisburg Pa This invention relates to devices attached to the tread of a vehicle tire for preventing skidding, and more particularly to that class of anti-skidding devices comprising separate semi circular sections coupled together around



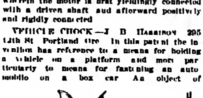
ANTI SKIDDING DEVICE FOR TIRES.

the tire at the tread and sides An object is to provide an anti skidding device consisting of a chain formed of sections as represented herewith in a side elevation of the invention as applied It further consists in novel features of the special automatic coupling link and its appurtenances in the special form of a link uniting the other sections in the chain and in the special form of the individual chain sections

SIGNAL DEVICE FOR VEHICLES.—C F Marston Great Neck Box 113 Cedarhurst L I New York In this instance use is made of a casing for attachment to the rear of an automobile or like vehicle and provided with an adequate signaling means connected with the brake mechanism of the vehicle so that when the brake is applied the signal will operate to inform the operator of a vehicle in the rear that the first vehicle is modifying its speed

GEARING FOR TRACTION ENGINES.—J T Metcalfe and G Metcalfe care of Quincy Engine Co Quincy Pa The object here is to provide a transmission especially adapted for use with explosive engines and capable of a plurality of forward and a reverse speed, wherein the motor is first yieldingly connected with a driven shaft and afterward positively and rigidly connected

VEHICLE CHOCK.—J B Harrison 295 12th St Portland Ore In this patent the invention has reference to a means for holding a vehicle on a platform and more particularly to means for fastening an automobile on a box car An object of



VEHICLE CHOCK

the invention is to provide a holding device which may be adjusted to fit different sized wheels, and to fit the sets of wheels disposed at different distances apart. In the illustration is a side elevation of an automobile mounted in a box car by means of the invention.

ELECTRIC LIGHTING DEVICE FOR MOTOR VEHICLE LAMPS.—H D Grinnell, care of Agricultural Nat. Bank, Pittsfield Mass. This improvement provides a device for lighting acetylene and other gas lamps of automobiles and other motor vehicles, in a very simple and convenient manner without stopping the vehicle or requiring the operator to leave the vehicle

PUNCTURE PROOF TIRE.—W McKay care of Dr I G Burton, 1181 Broadway New York N Y The aim in this instance is to provide a tire arranged to permit convenient assembling of the parts, and to protect the inner tube against being punctured by tacks or the like at the same time producing the desired cushioning effect of the ordinary inner tube tire.

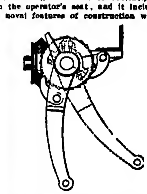
AUTOMATIC TRUCK BODY LIFTER.—L P Cole, Jr., 106 Jefferson St., Weehawken, N J The invention provides an automatic truck body lifter arranged to permit of lifting the body of the vehicle off the truck or chassis and supporting the said body while loading or unloading it, at the same time allowing using of the truck on another body or for other purposes

SPRING WHEEL.—J Luhn, P O. Box 377, Belpre Kan The improvement is in spring wheels, and the object of the invention is the provision of a simple, inexpensive device which while having approximately the resiliency of a pneumatic tire, will be devoid of the disadvantages of such tires.

SPRING CUSHIONED WHEEL.—S W Burckhin R. F D., No 2, Prague, Okla. The invention is an improved substitute for the pneumatic tired wheels commonly used on automobiles, autocycles, and other motor propelled vehicles. It is particularly an improvement in spring wheels in which a pneumatic outer tire is disposed with and an elastic central or hub portion is substituted to provide the required resiliency for the wheel as a whole

VEHICLE WHEEL.—T T Chaloner, 506 W 47th St Manhattan, New York, N Y The invention relates more particularly to a resilient wheel, and the object is to provide means for resiliently supporting an outer rim or tread member Also to provide a wheel structure formed with an outer rim supported by springs and a plurality of resilient plugs projecting beyond the rim

AUTOMOBILE STARTING DEVICE.—F Miskovsky 133 Brownell St., Providence, R I In the present patent the invention is a starting device for automobiles, by means of which the engine can be conveniently started from the operator's seat, and it includes certain novel features of construction which are



AUTOMOBILE STARTING DEVICE.

designed to minimize the liability of accident to the operator in case of backfiring, or the starting of the engine in the wrong direction In the accompanying engraving is a view of a side elevation of the starting mechanism of the device.

SUPPLEMENTAL SEAT ATTACHMENT FOR MOTORCYCLES BICYCLES AND LIKE MACHINES.—C W Duckworth 30 W Adams St Jacksonville Fla The invention provides an auxiliary frame carrying a foot rest and a handle bar the auxiliary frame being connected at its forward upper end with the frame of the bicycle or motor cycle and being yieldingly supported from the rear axle of the machine

Designs.

DESIGN FOR CARPET OR RUG.—J G Peirl, care of G S Squire 41 Union Square New York N Y The border and centerpiece of this carpet or rug design is decorative with geometrical figures of a very ornamental and original style and between these the field is freely patterned with flowers.

DESIGN FOR A SOCK OR STOCKING.—H E. Beers, Lord & Taylor, care of J C Lay 901 Broadway New York, N Y In this design for a sock or stocking the reinforced heel extends upward to double the usual height and ends in an ornamental point.

Note.—Copies of any of these patents will be furnished by the Scientific American for ten cents each Please state the name of the patentee, title of the invention, and date of this paper

Success of the County Agriculturist Plan

By Charles M. Carroll

THAT the farmers of this country are awakening to the necessity of employing modern, business-like methods in conducting their farms if they want to secure the best results, is becoming more apparent every day The rapidity with which County Agricultural Bureaus are being formed all over the United States is the best proof in the world that the men who till the soil are beginning to realize that antiquated methods and old-fashioned ideas have no more place on the farm than in any other field of work.

There are now about 100 County Farm Bureaus in active operation in the different States, as many more have organized, but are not yet employing county agents, while the total number of counties applying for information with a view to establishing agricultural associations is 603.

It was two years ago that the Council of Grain Exchanges conceived the idea of placing an agricultural expert and adviser to the farmers in every county in the United States. The Crop Improvement Committee, with Bert Ball as its secretary, was then formed, and the raising of a national fund to carry on the work was started This fund received a stimulus last spring in the shape of a million dollar donation from Julius Rosenwald of Chicago, who has set aside this sum, one thousand dollars of which is to go to each of the first thousand counties that are willing to co-operate in the work.

Two of the first counties to avail themselves of this offer were Kankakee County Illinois, and Pettis County Missouri While the two counties proceeded along similar lines in forming their associations, each has worked out certain individual details of peculiar advantage to itself The Crop Improvement Committee itself takes no active part in the organization of these Farm Bureaus, each county being left free to act as it sees fit. The committee simply recommends a line of procedure which will enable it and the county committee to make a satisfactory agreement

The farmers and business men of Kankakee County were quickly impressed with the great value of the Crop Improvement Committee's plan, and determined to win the notable honor of being the first county in the United States to qualify for one of the thousand-dollar donations. A few far sighted men behind the scheme had a dream of double crop production—of prosperity resulting from these bounteous yields that should make Kankakee County the best place in the world to live in. The idea caught the imagination of the people of Kankakee County Farmers, bankers, millers, manufacturers, joined hands to raise the money needed to put the bureau on a permanent basis and carry out the other conditions prescribed by the Crop Improvement Committee In less than two weeks more than $10 000 was raised and the organization, known as the Kankakee County Soil and Crop Improvement Association, was incorporated with a capital stock of $50,000.

Prof John S Collier, of the Agricultural Department of the University of Illinois, was engaged as the association's expert. His duties are to advise the farmers, individually and collectively, as to the best methods of cultivating their farms, to point out the troubles and prescribe the remedies, to organize clubs, associations, etc., to give practical farm demonstrations in crop rotation, soil building, farm management. In short, he has been employed by the association to show the farmers how to get more from the same amount of land and how to make what they produce of better quality.

Prof. Collier proposes to plat every farm in the county, and to have a complete history of each, together with a soil analysis. As there are about 2,800 farms in the county it will require some time to complete this task, and he is taking up the farms of the members of the association first.

INQUIRY COLUMN

Inquiry No. 9287 Wanted to buy a machine which will reduce cobs to meal—not a machine for shredding the cobs, but a machine that will pulverize them.

Inquiry No. 9288. Wanted the names and addresses of concerns that can coat steel balls with pure tin one-sixteenth of an inch thick.

Inquiry No. 9289. Wanted substance melting at 325° and hardening when cold without imparting any flavor to tobacco smoke and without emitting any oily or fatty vapors.

Inquiry No. 9290. Wanted name and address of a manufacturer of a patented device which is suitable for making up pay envelopes, namely, to fold up bills and insert them with minor coins in a pay envelope of the usual size.

Inquiry No. 9291 Want to buy machinery for manufacturing wooden bowl plates.

Inquiry No. 9292. Wanted, a gum that will stick labels to grape-fruit.

Inquiry No. 9293. Wanted the names and addresses of manufacturers of waterproof cloth, also samples of such cloth.

Inquiry No. 9294. Wanted to buy glass balls [illegible] in diameter.

Inquiry No. 9295. Wanted name and address of [illegible]

The county authorities have contributed the use, rent free, of four commodious rooms in Kankakee's new half million dollar county building as the association's headquarters. There are, in addition to Prof. Collier's private office, a large meeting room, a library containing several hundred books of agriculture, a rest room for the farmers' wives, and a large play ground for the farmers' children. A completely equipped agricultural laboratory has also been established in the Kankakee High School.

As soon as the association had been formed, work was started to form from ten to fifteen co-operators in each township in the county These co-operators send regular reports of the progress of crop improvement in the different townships to Prof. Collier Arrangements are now being made with the National Government whereby domestic science will be made part of the county farm bureau, the work to be in charge of a competent woman who shall make a study of home life throughout the county, and act as adviser to the farmers wives, as Prof Collier is doing with the farmers about their fields.

Usually the soil expert spends the larger part of half a day on each farm, going over each field and giving advice as to its management. Then there are numerous emergency calls to be attended to. One day it is a man who wants to know what to do for corn worms, the next it is a man who wants to know why his rye straw falls down

Another plan of the Kankakee farm bureau is the formation of a seed testing association, which will make it possible to insure clean tested seeds for every farmer in the county The idea is to erect a seed house in Kankakee, equipped with seed cleaning and seed grading machinery of the most approved type that no seed be accepted here except that grown by members of the association under its rules. In this way it is urged that the association would gain national prominence, second to none on earth, on account of the superiority of its seed. The estimate is made that clean and tested seed alone will add half a million dollars to the crop value of the county

The seed testing and seed selection work has been given a stimulus by getting the school children interested in it. By what is called the 'Rag Baby Test,' a ten-year-old boy or girl can quickly ascertain whether seed is good, bad or indifferent It is the plan of the Kankakee County farm bureau to widen the scope of this work among the children and put the little ones in competition with their fathers and older brothers.

The organization of a farm bureau in Pettis County, Missouri was due to the Boosters' Club of Sedalia Early in the history of the club its members realized that anything that could be done for the practical benefit of the county would redound to the benefit of the city, and with that idea in mind they promoted the building of rock roads, better livestock, more extensive dairying and improved methods of marketing

Sedalia is a city of about 21,000, and Pettis is regarded as one of the best counties in the State, having approximately 3,000 farmers whose lands vary in worth from \$50 to \$200 an acre. A close scrutiny of federal and State crop statistics, however, compelled the humiliating consciousness that Pettis County crop yields, particularly of corn and wheat, were much too low Why? Something was wrong What was the cause of this condition and how could it be remedied?

These questions confronted the club, and it decided that the farmers of the county would have to change their methods or quit farming. The conclusions drawn, after careful study, were that what the county needed and should have was the services of an expert, practical farm adviser.

About this time the State Board of Agriculture gave Pettis County a three-day institute date at Sedalia, with M. M. Jordan as the speaker. After hearing Mr. Jordan's lectures on corn and how to in-

crease its yield, the club decided that he was the man they wanted. The result was that they engaged him on the spot at a salary of $3,000 a year. Within six days much more than the required amount to put the bureau on a solid foundation was raised and the Pettis County Bureau of Agriculture was established. It now has a membership of over 500. There is not one of these members who is not of the opinion that should Mr Jordan die to-morrow, the county has already realized in the short space of eight months benefits five times his total cost for a year.

Before Pettis County got Mr Jordan there was a universal saying that "you can't grow alfalfa in Pettis County—we've tried it and know." Mr Jordan didn't believe it and has proved that it can be done. In over 200 soil tests he made, with a single exception, every one was sour—so acid that alfalfa would not grow. He showed the farmers how by the use of lime or ground limestone, 1,000 to 4,000 pounds per acre, their soil could be sweetened, then by thorough preparation and use of good seed they could grow alfalfa. More than forty Pettis County farmers sowed it last spring under Mr Jordan's direction, and in every case an excellent crop was obtained.

Through long continued "corning" of land, robbing the soil, scrub seed and scrubbier culture, the corn of Pettis County ran as low as 25 bushels per acre. Mr Jordan corrected this, all phases of it. He found that adulterated seeds were being sold in the county. He began testing seeds and quickly put a stop to this practice.

At the farms Mr Jordan visited several neighbors would assemble. This suggested holding institutes out on the farm with whole families in attendance, basket dinners and all-day affairs. These were held throughout the county, sometimes as many as 600 people being present on one farm. Frequently return dates were asked for.

Secretary Ball of the Crop Improvement Committee estimates that the amount required to run a county farm bureau will seldom exceed one per cent of the tillable land in the county but not less than $100 for each township.

"We advise raising a local fund of from $2 000 to $5,000 a year for at least two years," said Mr Ball. "There are so many things that can be done to develop the county and make the plan a success if money is available. We are not in favor of running it on the cheapest possible basis. We always advise getting the best man in sight and paying him what he is worth. I know of one county which pays its expert $4,000 a year. He undoubtedly will prove cheaper than the men other counties are hiring at $1,200 a year.

"Any county in the United States is eligible to one of our thousand-dollar donations. There are only three conditions. The citizens of a county must want such service, they must want it enough to be willing to put up part of the cost and to organize for systematic work, and they must contract for the service of an expert for at least two years.

"The National Government has made arrangements with us to go ahead and organize as many county farm bureaus as possible, and as soon as the federal appropriation is available it will take our place in the fund and pay possibly one half the expenses of the farm bureau in each county the second year and thereafter. We are also making arrangements whereby the direction of the county agriculturist will be merged in a State leader, who shall represent both the United States Government and the State Agricultural College."

The Green Tarnish on Lead Pipes

TO remove green tarnish from lead pipes and connections in bath rooms, employ a strong solution of yellow ammonium sulphide. This is harmless, and after its application the pipes should be made sightly by polishing with a dry cloth.

Coming Army Aeroplanes

By C. H. Claudy

After all necessary expenses are paid, and the present aeroplanes of the army provided with needed repairs, etc., the Signal Corps will have about $35,000 of the 1913 appropriation left for the purchase of new aeroplanes. This sum will buy not more than four, and probably not more than three new machines.

The past four years have been largely experimental so far as practical aviation in the army is concerned. The Signal Office, having the work in charge has been more concerned with the development of what was needed with the ascertaining of the possibilities of aviation as affecting the service than in the making of an aeronautical arm of the service fitted for offensive work. Out of the many experiments, the countless flights, the many changes made in machines, certain very definite plans have come into being and certain well defined ideas have grown. These plans and ideas will, in all probability be incorporated in the specifications for new Signal Corps aeroplanes, which will soon be published and on which aeroplane makers will be asked to submit bids.

Definite announcements cannot be made as to the contents of these specifications but it is very probable that the first and perhaps the most far reaching of the new requirements will provide that no aeroplane with a motor developing less than 80 horse-power will be considered. In other words, it is no longer the minimum power and the lightest motor which is desired but the lightest motor which will develop sufficient power to provide for emergencies and permit both speed and carrying ability.

The aeroplanes, which manufacturers will be invited to bid upon, will probably be required to possess stream line inclosed bodies, and this specification will be applied as rigorously to the biplane as to the monoplane. Both for the protection of the aviator and observer from wind and cold and in order to reduce head resistance the inclosed type of body is now thought to be advisable.

Pictures of the Curtiss flying boat purchased by the Signal Corps for army experiments show something of what an inclosed body looks like. The flying boat however has a larger and clumsier inclosure than is wanted on the new aeroplanes, which are not required to be capable of running upon the water.

As revolutionary as anything in army flying machines anywhere in the world, will be the requirement that the new machines be armored. Experiments are now being made to determine the minimum thickness and weight of the finest laminated chrome steel armor, designed for aeroplane use. This chrome steel armor must be thick enough to protect the aviator from rifle fire at a height of two thousand feet or a range of two thousand feet at an angle up to forty five degrees, yet thin enough not to impede the carrying capacity of the craft.

An attempt will be made to equip the new aeroplanes with a radio-telegraphic apparatus, to be supplied by the Signal Corps itself the only requirement regarding it for the aeroplane builder being, perhaps, the incorporation of a generator with the flywheel of the motor and the provision for the carrying of the weight of the apparatus. The Signal Corps has succeeded in sending radio messages from an aeroplane for a distance of fifteen miles. So far no success whatever has been had with attempts to receive any wireless messages in an aeroplane, the noise of the motor, of the chains, when the propellers are chain driven, and the rush of air from the propellers, making the feeble beats of the message in the telephone headpiece completely inaudible. It is not improbable that at some future time some sort of pillowed headdress may, in conjunction with a well muffled engine, permit wireless messages to be received in the aeroplane. But the design will want some working out. It is pointed out that the problem is one of acoustics

and not of an electrical nature, and that any headdress which could be worn in an aeroplane, for noise-deadening purposes would necessarily be both large, cumbersome and in warm weather rather uncomfortable to wear.

It is expected that the new aeroplanes will all be equipped by the makers with a tachometer, a compass, an aneroid, a barograph, a map holder, a pad and pencil holder and a clock, and that the maker will provide the weight-carrying ability necessary to take care of these things. Two-place machines generally are desired for Signal Corps use and a minimum speed of forty miles is probable. Fuel and oil capacity will probably be required for at least four hours flight and undoubtedly the old style of endurance tests will have to give way to the modern idea of cross-country tests. Builders must make machines in which they are not afraid to risk themselves across country, rather than those which they are confident will stand up well in four hours circling of a parade ground. One man control will give way to dual control, so that either observer or pilot can manage the machine and undoubtedly there will be fair restrictions made as to climbing ability and quick starting. Probably the former will not exceed 2,000 feet in ten minutes nor the latter be more severe than is indicated in the ability to rise from plowed ground or a long grass field in 100 yards distance.

Agriculture at Columbia University

GENTLEMEN farmers of New York city are not generally supposed to know much about the actual methods used on their out-of-town places. About all they know is that vegetables are raised on them, are supplied to the table in the summer, and that the cost has not been many times the amount they would have to pay to the country farmer in their neighborhood. When the question arises as to the proper handling of the land under cultivation an expert is called in to give his opinion, a big fee is paid him and the land works well for a few years, when again the expert is called in and the proper treatment is advised again. This is about as expensive a method of farming as could be imagined, yet it is going on all the time on hundreds of country places near New York.

To meet this state of affairs the Department of Agriculture at Columbia is holding a series of lectures by men of scientific training and attainment—in fact by the very men who are called in from time to time by the gentlemen farmers—on Tuesday afternoons up to March 11th, at 4:10 P. M. While these lectures are necessarily scientific, they are divested, as much as possible, of technicalities and the New York farmer may easily learn the proper conduct of his farm. The lecturers are drawn from the national or State agricultural departments and from the schools of agriculture all over the country, many of them having farms of their own upon which the most advanced methods of farming are being carried out.

The aim of the course, which has been arranged by O. S. Morgan, professor of agriculture at the university, is to give chief consideration to the fundamental, practical aspects of the various phases of farming that should be weighed by every farmer manipulating land for crop or animal production about New York city. The competent housewife is always able to secure and keep better servants, so the gentleman farmer, who knows the subject, will be able to make his farm a greater success by use of the facts to be learned at these lectures.

Removing Paint From Glass

TO remove paint from glass a strong and hot solution of acetic acid should be applied with a cloth. As this is very effective care should be taken that the solution does not touch painted wood surfaces. The solution is harmless to the hands and may be applied directly to the glass from a cloth steeped in the solution.

The Planets in February

(Concluded from page 118.)

above, is now easily visible low in the south. A line from Betelgeux in Orion through Sirius, carried as far again, points it out.

The lines in its spectrum are not very strong, and it would be difficult to observe them visually without powerful instrumental aid. Gamma Velorum (Argo Navis) just visible on a clear night, some 8 degrees farther down, is a more promising object for the amateur, for its spectrum is of the "fifth type" and shows a broad bright band coinciding in position with the blue line of the principal series of hydrogen. This is so bright that it can be seen with a direct vision spectroscope placed over the eye-piece of a telescope of moderate size.

The Planets.

Mercury is in conjunction with the Sun—behind him—on the 12th, and is practically invisible during February. Venus is splendidly placed in the evening sky, being at greatest elongation on the 12th, 47 degrees from the Sun, and remaining in sight till 9:15 P. M. With the telescope she appears as a perfect half moon and to the eye she exceeds Sirius tenfold in brightness. Mars is morning star in Capricornus, rising about 5:20 A. M. at the end of the month. Jupiter is also a morning star, but is farther west than Mars, in Sagittarius, and rises about 3:45 A. M. on the 28th.

Saturn is in Taurus, well past opposition, but conspicuous in the evening sky. He is in quadrature with the Sun on the 10th and crosses the meridian at 6 P. M.

Uranus is morning star in Capricornus, and is observable only at the end of the month. He is in conjunction with Mars on the 25th, being 20 minutes north of the ruddy planet. This would be a good time to find him if only the necessary hour of observation were more convenient.

Neptune is in Gemini and comes to the meridian about 10 P. M.

The Moon is new at midnight on the 5th, in her first quarter at 4 A. M. on the 14th, full at 9 P. M. on the 20th, and in her last quarter at 4 P. M. on the 27th. She is nearest us on the 21st and farthest away on the 7th. Since full Moon coincides so nearly with perigee, the tides will run high about that date.

During the month the Moon comes into conjunction with Jupiter on the 2nd, Mars on the 3rd, Uranus on the 4th, Mercury on the 5th, Venus on the 10th, Saturn on the 11th, and Neptune on the 18th, none of the observable approaches being close.

Princeton University Observatory.

Clarifying Beer by Gelatinous Silica

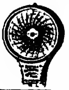
SUCCESSFUL attempts have been made by P. Deprax, according to *Les Ann. de la Brass. et de la Dist.* to clarify beer by means of gelatinous silica, especially those dense beers which are difficult to clarify by the use of fish glue.

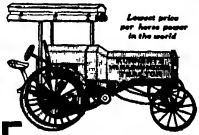
One hundred grammes of the jelly containing 17 per cent of the dry silica are sufficient to clarify one hectoliter of beer in the course of ten hours.

Since large "doses" of this substance may be used without inconvenience the process may be hastened by the employment of a double quantity, in which case the required time is much less. Other advantages of this agent are its very low cost, and that there is no danger of introducing by its use putrescible substances into the liquid to be purified.

The Mississippi as a Conveyer of Material

FROM a large number of analyses of the waters of the Mississippi River it is estimated that the great stream carries annually into the sea during the average year, 136,400,000 tons of dissolved salts, and 340,000,000 tons of mud and other suspended matter—a total of 476,400,000 tons of material extracted by the Mississippi and its tributaries from the rocks and soils of its drainage basin.





Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books *etc* This will greatly facilitate answering your questions, as in many cases they have to be referred to experts The full name and address should be given on every sheet No attention will be paid to unsigned queries Full hints to correspondents are printed from time to time and will be mailed on request

(12737) A A C asks Will you kindly give directions through the Notes and Queries column for filling a barometer tube accurately using only such apparatus as is found in a good high school laboratory? A The usual method of removing the air bubbles from the mercury in a barometer tube is to take a piece of iron wire—No 24 Brown & Sharpe will answer the purpose—and wind one end of it around a short piece of cotton wicking Run this to the bottom of the tube It should pass somewhat loosely so that the mercury will flow past the wicking Now fill the tube with mercury and draw the wire up the tube The cotton wicking will sweep the air bubbles off the glass The wire may be run down the tube and drawn up any number of times till the bubbles are all removed Another way of making the swab has recently been described Wind one end of an iron wire into a spiral which is somewhat smaller than the bore of the barometer tube Into the turns of this spiral pass some soft cotton wicking and proceed as before This seems to be an improvement because the wire will fit the tube better and the mercury will run through the middle of the spiral better than past the wad of cotton as described above

(12738) G F C asks In which of the three classes of levers does the claw hammer belong? A In a claw hammer the power is applied by the hand on the handle of the hammer the weight is the resistance of the nail to be drawn and the fulcrum changes along the back of the hammer as the nail is pulled out This you will see makes it a lever of the first class. If your question refers to the use of a hammer in giving a blow it was not necessary to specify a *claw* hammer and the answer is not the same. The weight to be moved is the head of the hammer The power and the fulcrum are both in the hand If you regard the hammer as moving on the thumb side of the hand then that side of the hand is the fulcrum, and the power is applied with the fulcrum in the middle, and the lever is of the first class If you regard the hammer as moving on the opposite side of the hand as a fulcrum, it is a lever of the third class with the power between the fulcrum and the weight It is wholly as you regard the action of rotating the hammer on the hand The best way to settle such a question is to try it and see Watch some one striking with a hammer Your request for the answer in the *next* issue of the paper is a very common one You will see however that most of the paper must be written some time before it is published It must be set into type made up into pages, proof read and corrected printed folded wrapped addressed and mailed so as to reach the subscriber on the day of publication as it is dated All this takes nearly or quite a week of hard work for the editorial and office forces Only when something very unusual happens is the work stopped to insert it as a special item.

(12739) W B asks 1 Do I understand aright that in the summer months in northern latitudes say Albany the sun rises apparently north of east? In other words that the sun will shine on the north elevation of a building standing directly east and west both morning and evening If so please explain in a layman's vernacular A It is quite true that the sun in the summer half of the year from March 21st to September 21st rises to the north of the east point of the horizon and sets to the north of the west point of the horizon, so that it is above the horizon longer than it is below and the daytimes are longer than the nighttimes. The sun shines near its rising and setting on the north walls of houses which face north and south during all this period. If you have never noticed this you can easily verify this apparent motion by observing the point on the horizon where the sun rises or sets for the next year You will see that point advance toward the north till June 21st and then retrace its path to the south until the 21st of next December The sun is the center of the earth's motion during the year and the axis of the earth is inclined nearly 23 degrees 30 minutes to the plane of the earth's orbit. This causes an apparent shifting of the place of the sun north and south since the axis of the earth is always in the same absolute direction in space, or nearly so The north pole of the earth is directed more toward the sun in June than in December by 47 degrees, or twice 23 degrees 30 minutes. 2 Also explain why although the shortest day is on December 21st the sun begins to set at a later period four days previous, that is, why do the evenings grow longer sooner than the mornings in this part of the year? I inclose copy of calendar which shows sunrise and sunset during December, with notations of length of days in hours and minutes A The second question, as to the change of sunrise near December 21st, is answered by saying that the clock and the sun are together but four times in a year and noon or midday, at all other times is either before or after twelve by the clock. Clocks do not keep the time of the sun which we see, but of an imaginary sun which moves regularly around the sky in a year This is necessary because the real sun does not move uniformly, but is going fastest at this season of the year and slowest about July 1st. Clocks cannot keep with a sun which moves irregularly hence they are made to go regularly and they go ahead or fall behind the sun as may be the case. Only four times in a year are the clocks with the sun There are two causes of this irregularity of the apparent motion of the sun The first is that the motion of the earth around the sun is not regular It is going fastest about January 1st and slowest about July 1st The second is that the day's marches of the earth are reckoned on the equator of the heavens while the earth actually moves in the ecliptic The combination of these two causes produces the result we have described Midday or true noon by the real sun is always midway between sunrise and sunset but 12 by the clock is not midway between sunrise and sunset excepting on four days of the year December 24th is one of those days. The sun rose at 7 17 or 4 hours 43 minutes before 12 and set at 4 43 after 12 The morning and afternoon were of the same length The time by which the clock is away from the sun is called the Equation of Time and may be found in any good astronomy We recommend that you read Todd's New Astronomy which we send for $1 48 You will find all these questions explained in that book and we think you will be much interested in it We are not able to explain these matters except in the language of astronomy although we hope we have avoided unfamiliar technical terms.

(12740) R E P asks I will be obliged if you will answer the following question in your Notes and Queries column Is it better to keep a watch running continually or to let it run down and rest during periods when not in use? A Watchmakers always say that a watch should not be allowed to run down and lie without running The principal reason seems to be that the oil will gum upon the works and when the watch is started it will not keep good time until it is cleaned and oiled

(12741) P S F asks During the night of January 2nd after several hours of rain there fell about four inches of snow here the first snow fall of the winter On top of this snow were thousands of angle worms scattered in some places in other places quite thick One place I counted fifty on a space ten feet square Where did these worms come from? They could not possibly have crawled up through the snow If they did *not* crawl up out of the earth they must have fallen there Is there any scientist that can answer this question or will the answer be just a theory? A We cannot account for the fall of worms as described in your letter Such instances have been reported in other places Small frogs and little toads are said to have fallen as well as worms They may have been taken up in some other places and fallen out of the cloud at your place It is not probable that a scientist can give any better explanation of such a matter than a common-sense man

(12742) R K asks Will you please tell me where I can find information in regard to generating electricity from steam or compressed air or from heat? I have been experimenting with steam but have not accomplished anything practical yet Any information you can give me will be greatly appreciated A All electricity for light and power is generated by the use of steam engines or water power Any book upon the steam engine will be in the line of your question But if you want a book upon the direct generation of electricity from steam or compressed air or directly from coal we must say that nothing has been accomplished in these lines, although much time and money have been spent in the search for such a method of producing electricity In the back numbers of our SUPPLEMENT you will find articles telling of these researches We send you a catalogue, and shall be pleased to supply you with any numbers you may order

(12744) H P asks Will you be kind enough to answer the question below by mail and oblige? Some time ago a corps of engineers in running a line for a railroad came to a point where the needle refused to work, the ground was elevated, and repeated trials brought the same results On the elevated point the needle would dance and could not be kept still or reliable The ground is underlain with iron ore but this has never before affected the usefulness of a compass I would very much appreciate a reply or some explanation A We are not able to explain what you write about the behavior of a compass needle in a certain place over iron ore There is no reason why a needle should 'dance' or refuse to come to rest in such a place, but it would not come to rest in a correct direction It would be deflected to the east or west Nor can we explain why the needle should have been reliable in this place before and not on this occasion A compass needle is usually deviated from its proper position by iron ore in the earth near the surface, but not with such behavior as you describe. The line run by the compass in such positions simply wanders farther and farther away from its correct direction and the error becomes greater and greater till the survey is of no value.

NEW BOOKS, ETC.

ENGLISH LITERATURE MEDIEVAL. By W P Ker, M.A New York: Henry Holt & Co 16mo, 256 pp. Price, 50 cents net.

HERALDS OF THE MORNING The Meaning of the Social and Political Problems of To-day and the Significance of the Great Phenomena in Nature. By Asa Oscar Tait. Mountain View, California Pacific Press Publishing Association, 1912. 8vo, 419 pp, illustrated.

OFFICIAL AMERICAN TEXTILE DIRECTORY, 1912-1913. Compiled by the Textile World Record Boston Lord & Nagle Company 8vo., 664 pp Price, office edition, $3, travelers' edition, $2

We have before taken occasion to mention favorably this textile directory which is published annually in July The present issue maintains the standard of fullness and accuracy that has marked former issues. There are reports of all the textile manufacturing establishments of the United States and Canada together with a yarn trade index and lists of concerns selling to or buying from textile mills. More than 13,000 different concerns are listed there are 23 maps and a vast amount of further information is so presented classified and indexed as to make the work invaluable to those who require some such volume of reference.

MODERN ORGANIZATION By Charles Delano Hine New York The Engineering Magazine Company, 1912 Price $2

In this excellent little book the republication in permanent form of a series of articles on the unit system prepared by Major Hine for the *Engineering Magazine* we have a most interesting and instructive description of the system that Mr Julius Kruttschnitt has introduced on the Harriman Railway Lines comprising about eighteen thousand miles of railway employing between eighty thousand and one hundred thousand men and women and earning annually about $225,000,000 Obviously so vast a system must be most efficiently organized if it is to operate with success That it does operate with success is a matter of common knowledge. How that end has been attained is one of the chief objects that Major Hine has undertaken to set forth In the brief space of this review it is impossible to unfold the method whereby success was achieved. Suffice it to say that it lies in the decentralization of detailed activity and substituting for it centralized control In a felicitously worded preface to the book Mr Charles Buxton Going the editor of the *Engineering Magazine* points out very aptly that the policies advocated are most interesting because they depend so little upon mechanisms of any kind so little upon system affecting rank and file or the equipment and material and so much upon psychological influences operating first upon and then through the directing officials.

THE NEW INDUSTRIAL DAY By William C Redfield New York The Century Company, 1912 Price, $1 25 net

If anyone needs to be convinced that American manufacturers are on the whole a healthy-minded set of men surely the literature on efficiency engineering and scientific management which has appeared within the last few years and which has been eagerly bought and read gives ample evidence of it. Like most of his predecessors Mr Redfield is more philosophic than practical in his treatment of efficiency Therein to our mind lies its chief value No two industries are so exactly alike that the application of efficiency principles to one is a guarantee of their success when applied to the other Therefore what is wanted is an optimistic, stimulating exposition of correct sociological views, a vivid presentation of the relation that should exist between employer and employee and a correct estimate of the debt that the body politic owes to the manufacturer and the manufacturer to the body politic Mr Redfield's book shows how necessary it is to imbue each man engaged in business or manufacturing with the idea that he is but a single element in a vast piece of machinery the perfect operation of which depends in a certain measure upon his efficiency on his sense of social justice, on his conscience.

DACTYLOGRAPHY OR THE STUDY OF FINGER-PRINTS. By Henry Faulds. Halifax Milner & Co, 1912. Illustrated.

In this excellently written book we find a very clear and compact presentation of the whole subject of finger prints, including its history as well as its practical application. The subject is becoming of such increasing importance (finger prints are now used not only by the police for the detection of criminals, but also by the army authorities for the identification of deserters and by banks as a check against forgery) that a popular yet accurate book is really needed. This Mr Faulds has supplied.

MODERN ILLUMINATION Theory and Practice. By Henry C Horstman and Victor H Tousley Chicago Frederick J Drake & Co., 1912. 12mo., 273 pp, illustrated Price, $1 50.

Theory is here everywhere subordinated to the conditions of practice, the aim being to aid electricians architects, and those interested in commercial and industrial establishments, rather than to furnish a text-book for the student or theorist. The material has been arranged with this object in view and the principles of light and illumination are discussed only so far as is necessary to a practical consideration of special conditions. In addition to installation and location of lamps, there are chapters dealing with the color of light, the choice of lamps, the choice of fixtures, and indirect lighting. Apartment buildings, ar-

cades armories studios art galleries ball rooms all have consideration as to the particular system of lighting best adapted to their peculiarities and a table of intensities is appended The chapter on plans and specifications also contains a great deal of valuable information

Le Calcul des Probabilites et ses Applications Par E Carvallo Directeur des Etudes a l'Ecole Polytechnique Paris Gauthier-Villars 1912

In the calculus of probabilities mathematical difficulties are only too abundant To avoid them they must be known The theory of games furnishes all that can be desired in the way of problems since the arbitrary combinations are unlimited Here we have a rich crop of ingenious devices of elegant solutions of surprising paradoxes Fortunately if their attractions are great for mathematicians their utter uselessness is certain for the majority of investigators The author has therefore suppressed entirely the theory of games Only a few examples have been retained which by reason of their simplicity are amenable to definition and to ready explanation Much of the book is devoted to the methods of statisticians Naturally the theorem of Bernoulli plays an important part in the discussion To follow that discussion the reader must be something of a mathematician Yet despite that requisite the book is interesting reading even for the general reader

The Spell of England By Julia de Wolf Addison Boston L C Page & Co 1912 8vo 433 pp illustrated Price $2 50 net

The Spell of England is one of the best volumes of The Spell Series which is saying a great deal Possibly the author's childhood in England is partially responsible for the sympathetic treatment But this must of course have been supplemented by mature observation and judgment before so intimate a description covering so wide a territory could be written The volume is replete with humor as well as with charm Indeed refined characteristic humor has always a charm of its own and there is never too much of it History scenery modern manners architecture—all are treated lightly briefly yet lovingly and the result is a very readable and instructive work The illustrations from special photographs are always a feature of this series and those in hand are fully up to the standard The frontispiece in colors of Caesar's Tower Warwick Castle is a particularly faithful and beautiful reproduction

Roads Paths and Bridges By Logan Waller Page New York Sturgis & Walton Company 1912 16mo 263 pp illustrated Price 75 cents net

Mr Page is director United States Office of Public Roads president American Association for Highway Improvement and a member of the American Society of Civil Engineers With all these qualifications he should be able to impart some very instructive information on a topic of the most vital importance to the country at large And within the scope of so compact a work Mr Page has fulfilled all expectations He truthfully says at the beginning that road building is an art based upon a science A deep knowledge of any art or any science can be acquired only at the expense of years of study and practical application But the farmer and the country gentleman may find even a superficial knowledge provided it be grounded in true principle most useful and beneficial And it is with this particular end in view that the author writes Locations surveys plans and specifications are made the subject of an early chapter This is followed by chapters on the various kinds of roads—earth sand-clay gravel broken stone and macadam Maintenance and repair receive the attention worthy of so important a branch of the subject and a paper on the construction of culverts and bridges concludes a most useful and practical work

The American in Panama By William R Scott 5×7½ in 258 pp 28 illustrations New York Statler Publishing Company

We give our hearty commendation to this interesting and illuminating work by a former employee of the Isthmian Canal Commission The book shows the great advantage we had almost said the necessity of anyone who writes a book about the Panama Canal doing so from the inside and on the spot Mr Scott tells us he discovered that had he followed the usual method of coming into the Canal Zone on the steamer taking notes and leaving on the next steamer he would have missed many fundamental facts which absolutely must be known if a really trustworthy account of the work is to be given He is correct also in his belief that the average American layman desires an authoritative history of the project, and that he particularly desires a non technical review one which distinguishes events from mere incidents and that is not burdened with a mass of details which make it difficult to keep in mind the essential facts. The work opens with a historical review of the history of events at Panama under the Spanish, French and American occupation. Credit is given to President Roosevelt for the great impetus which he gave to this work The author is not pleased with the moral aspect of Mr Roosevelt's settlement of the political difficulties as he makes very clear in a chapter entitled Taking the Canal Zone The development of the work is traced first under Wallace then under Stevens, and finally under Goethals Credit is given to the first two for blazing the way and particularly to Stevens for outlining what is practically the present organization and method of doing the work. Not very much space and yet sufficient for the purpose of the book is devoted to a technical description of the dams and locks and the big cut at Culebra, and the work closes with a very readable chapter on the Monroe Doctrine.

The Scientific American Medal

(Concluded from page 111.)

quently Most of the cases were gas poisoning, but two of the patients were revived from the effects of an over-dose of morphine, two were revived after serious operations, and one case of electric shock was successfully encountered. Public corporations, like the New York Edison Company and the Consolidated Gas Company, put these wonderful machines at the *service of the public day and night* for the purpose of saving life The generosity of some of the large corporations, like the New York Edison Company, in maintaining these life-saving devices for the use of those who are in dire necessity is particularly to be commended, especially in view of the fact that time is everything and the speedy transportation by an automobile must be provided for if there is to be any chance of success

Prof Hutton continued

"The second *gold medal is the gift of* the Travelers Insurance Company, and is for such American employer as has done most for the protection of his work people in limb and life

Such dangers are insistently present in the great electric generating power houses, where energy far surpassing that of the electrocution process is generated second by second and where the human organism is but an atom in the path of enormous mechanical energies For persistent determination to minimize these dangers where engineering and administrative foresight could intervene to prevent them the New York Edison Company has a position in the foremost rank It is for that effort and success as revealed in their many power houses in Greater New York that the Travelers Medal is this year awarded There is also much of mutuality and educational work conducted at the company's expense and availed of in the company's time which while emphatically present in the administration of this company cannot be specifically covered at this time

The third gold medal is the Dr Louis Livingston Seaman gift for progress and achievement in hygiene and sanitation and the mitigation of occupational disease

There are certain industries where the worker comes in contact with poisonous or deleterious substances these are called the dangerous trades and include dusty trades the manufacture of matches lead paint gas and chemical products But even in the strictly mechanical and in noxious productive establishments where many are gathered together communicable disease is always present and the maleficent germs will be conveyed It has therefore seemed to the Museum that it was no less an achievement to clean up a factory than a Canal Zone, and make it a healthy place in which to work.

For their success in securing pure air to breathe pure water to drink, abundant light to work by and personal cleanliness of body, the National Cash Register Company of *Dayton, Ohio,* are *pre-eminent* For these achievements in hygiene and sanitation the Seaman Medal is this year awarded to the National Cash Register Company

"The last gold medal of the series is the gift of the Allgemeine Electricitaets Gesellschaft, Berlin, known as the Rathenau Medal in honor of its distinguished president Dr Emil Rathenau, and is for the best device in the electrical industry for safeguarding industrial life and health"

It was awarded for the Edison safety storage battery and lamp described in our last issue

Dr Hutton's formula of presentation was most impressive.

"By the authority of the State of New York, conferred by charter on the American Museum of Safety, and by direction of its Board of Trustees, as one of the vice-presidents of such board and in its name, I do now confer these medals."

The exercises were concluded by an exhibition of lantern slides showing graphically some of the [illegible] for the awards. The director, Dr. W. H. Tolman, [illegible]

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest If the photographs are sharp, the articles short and the facts authentic the contributions will receive special attention Accepted articles will be paid for at regular space rates

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

Col. Goethals on the Culebra Slides

IN the course of a recent interview, Col Goethals assured us that he had no anxiety whatever with regard to the more serious problems on the Panama Canal The dam at Gatun is completed practically to its full height, and with a head of over fifty feet of water against the upstream face for the past few months, it has proved to be both stable and proof against seepage, and the central core of impervious hydraulically deposited material is drying out and solidifying satisfactorily The approach wall which had shown a disposition to settle has been straightened and is now secure against any further movement

"But what about the unstable conditions at the Culebra Cut?" "We expect further slides there said the Colonel, "some big slides, in fact and they may occur before I got back to the Isthmus. But they are not giving me anxiety, nor will they cause any interruption to traffic after the Canal is opened I have ordered two floating dredges of fifteen yard bucket capacity, to be delivered in December, each of which can take out from 400,000 to 600,000 cubic yards of material per month."

The expected slides have already occurred. The old Cucaracha slide, which was supposed to be dead beyond resurrection has come to life and sent down 400,000 cubic yards into the Canal burying five of the tracks. Cucaracha is just to the south of Gold Hill and a few days later 500,000 cubic yards of rock and clay broke away from Gold Hill itself, leaving a cliff which is expected to contribute to another half million cubic yards. Purple Hill to the south of Cucaracha, has been weakened' on its north face and another million yards may add its quota from this source A mile or two north of this point another slide has developed, which may send down some two or three hundred thousand cubic yards into the cut

All of which looks very serious, indeed, if we lose our sense of proportion, but if the slides are big, so is the capacity of the excavating plant The steam shovels will keep the prism free until the cut is water filled, and then the two new dredges referred to above, each capable of taking out some twenty tons of material at a single scoop, and removing between them a million cubic yards per month or more, will easily control the situation until Culebra shall finally cease to slide.

State Versus Federal Control of the National Forests

BECAUSE to be forwarned is to be forearmed, the SCIENTIFIC AMERICAN wishes with great emphasis to draw attention to the fact that a strong movement is on foot throughout certain sections of the country, and in Congress itself, to break down the system of national forest protection, by turning the national forests over to the States. Such a movement if successful, would be a blow not only to forest protection, but to the whole movement for the conservation of the national resources of the United States.

One of the finest accomplishments of the Roosevelt administration was the legislation which was designed to protect the national resources of the country and secure their future preservation and wise and equitable development This legislation met the national demand that the private exploitation of the forests, water powers and mineral lands of the country be abolished or at least controlled. It was realized that such control should be exercised, not by the various States in which the natural resources happened to be located, but directly and solely by the Federal Government.

Although the movement in favor of conservation was national in its scope and popularity, it aroused the bitter antagonism of those vested interests, which, under the old conditions were able to acquire and exploit the nation's resources to their own personal and enormous profit The friends of conservation have realized from the very first that it was only a question of time when these interests would join in a concerted and active movement for the modification, if not for the repeal of the recently-enacted laws. At the present time, the agitation has taken the form of a struggle to remove the national forests from federal control and cede them to the States in which they are located. The movement, which has been growing in strength during the past few months, first assumed serious proportions about four years ago, when State versus Federal control of the natural resources was made a plank in many of the State platforms. That great activity is being displayed will be realized when it is stated that during the present Congress fourteen bills have been introduced, which are aimed more or less directly at transferring to the States the natural resources which are now under Federal control The policy advocated in these bills has been openly and strongly supported by many members in Congress.

The sure way to defeat this conspiracy is to give it the widest publicity and inform the general public as to the true facts of the case So far as the national forests are concerned, there are two principal reasons why they should not be turned over to the western States. One is that the step would involve a waste of money and effort, and the other is that the States are not furnished for the task. State control of the forests in the past, indeed, has not only been incompetent, but (and this is a much more serious matter), it has not been done with a single eye to the public interest.

The arguments against State control has a twofold aspect In the first place, the national forests and indeed all national resources do not concern merely the interests of the one section of the country in which they lie Rivers and forests, mineral veins and meadows, the cattle ranges and the public land itself, do not stop at the State line Certainly their administration in the interests of all the people of the country cannot stop at the State line If their usefulness is to be developed to the fullest degree and for the benefit of the whole people and the whole country they must be administered under national policies, decided from the national point of view

The other argument for Federal control is based upon the undeniable fact that, if the natural resources were placed under State control, we should be subjected in an extreme degree to that political spoliation, which has already robbed the country of so much of its birth right

Is it not a significant fact that the most bitter opposition to conservation comes from people who have an immediate or prospective interest in the personal acquisition of timber land, coal water power, grazing, or any other of the natural resources belonging to the people at large? Why are these gentlemen such ardent advocates of State control? Why are they so reluctant to leave the control in the hands of the Federal authorities. Can they blame the country at large if it looks with suspicion upon arguments for State control, which it is asked to believe are based solely upon the abstract principle of State rights?

The Automatic and Inherent Stability of Aeroplanes.

WHILE automatic transverse stability is much to be desired in aeroplanes, fore-and-aft or longitudinal stability is of greater importance, as nearly all the fatal accidents due to faulty stability, occur as a result of diving, which would not happen, or at least would be corrected, if aeroplanes had sufficient longitudinal stability, or if they were provided with suitable devices to bring them automatically back to a level keel Some attempts have been made to construct such devices, and one of them—the Doutre stabilizer—has been found to work fairly well, but of late more attention has been given to designing machines which will have inherent stability to a large degree, and thus will not depend upon automatic devices, which may sometimes fail, for the maintenance of equilibrium.

Early examples of the two methods of producing lateral balance are a V-shaped body and dihedral angle of the wings, typified in the Antoinette monoplane, and the use of a gyroscope as proposed by Maxim and others many years ago.

Recently Elmer A Sperry has brought out a method of automatic operation of the elevator and ailerons by means of compressed air, the air valves being controlled by two tiny gyroscopes weighing 2½ pounds each. Owing to the great sensitiveness of the gyroscope, the aeroplane can be kept on a practically even keel at all times, and also, according to Mr. Sperry, can be given automatically the proper banking on the curves.

Probably the first idea that comes to the average inventor who attempts to construct a system of automatic stability for aeroplanes, is that of the pendulum. A low center of gravity naturally tends to make an aeroplane stable, but the Wrights claimed that in connection with a dihedral angle it would produce rolling, which might become severe enough to capsize the machine. Consequently flexible wing tips and trailing edges were used instead by such men as Etrich, whose monoplane was described in SUPPLEMENT, No. 1933. These work very well, but later developments suggest that the center of gravity can be placed low without the serious consequences predicted In the latest hydro-aeroplanes of the flying boat type, notably the huge machine built by Voisin for M. Deutsch de la Meurthe (which has carried seven men for about an hour), the center of gravity is very low since most of the weight is in the boat-like body below the planes, yet these machines have excellent stability

The Moreau brothers, in France, early began experiments with a pendulum seat for the purpose of working the horizontal rudder and maintaining the fore-and-aft stability Their experiments have met with success for some time past, and the French government has recently purchased one of their monoplanes such as we illustrate and describe on another page. The Wrights also have patented an automatic stability device depending on a pendulum, but it has not yet been put on any of their commercial biplanes. A number of the French military biplanes are equipped with Doutre stabilizers, which also maintain the fore-and-aft stability automatically This device consists of a rectangular vertical plate which is moved back and forth by the varying air pressure, and which operates valves enabling compressed air to set the elevator properly It has been fully described in these columns. The French constructor, Sommer, has recently brought out an improved device of this kind also.

Even better than the aeroplanes equipped with automatic stabilizers are those which are inherently stable, owing to their shape. Foremost among such machines are the biplanes and monoplanes of Lieut. Dunne of England, which have given some noteworthy performances such as flying without human control for a quarter of an hour or more. The Dunne machines are V shaped in plan, the apex of the V being at the front and there being no rudders or tail. The wings slope downwardly to the rear in an inverse dihedral, and besides they have a constantly varying camber from the apex of the V to its ends.

The most recent machine having automatic stability is the Drzewiecki following-surface monoplane which was exhibited at the last Paris Salon This machine is of the Langley type. Its chief point of interest is that the wings forming the following surface are set at a 3-degree less angle with the horizontal than are those of the front surface. The result is as great a lift from the rear plane as from the front one and the production of righting couples that counteract diving and keep the machine on an even keel The machine was designed as the result of experiments made in the Eiffel aerodynamic laboratory It has not been tested to any extent up to the present Mr Robert D Andrews, in this country, conceived a glider along similar lines, and has tested it in small models with encouraging results. His rear surface is placed at a negative angle with the horizontal and the ends of the planes are connected together The principle is different from the Drzewiecki, but the result is similar in the production of automatic stability An account of the Drzewiecki machine appears on page 187, and full details of the experiments that led up to its construction are given in the current SUPPLEMENT

A Bill to Increase Patent Fees

IT is difficult to understand why it is necessary to increase filing fees in patent applications from $15 to $20, as proposed by Mr Bulkley in a bill recently introduced by him in the House of Representatives. Up to the present time about $7,000,000 has been earned by the United States Patent Office in fees, and turned into the Treasury of the United States. Obviously the Patent Office is not in need of money, it more than earns enough to pay for the cost of examining patent cases. If anything, inventors' fees should be reduced, for it is certainly not a function of Government to make money out of a class of men who enrich this country by hundreds of millions of dollars and many of whom begin their careers in anything but easy circumstances.

Record Altitude of a Sounding-balloon.—It is reported that a sounding-balloon sent up from the Observatory of Pavia, the headquarters of upper-air research in Italy, attained the unprecedented altitude of 23.4 miles. The previous record, 20.15 miles, was made at the Royal Observatory of Belgium, June 9th, 1911 The American record, 18.94 miles, was made at Huron, S. D., September 1st, 1910.

Electricity

Wireless to Germany.—The first wireless message sent direct from the United States to Germany was sent on January 17th from Sayville, Long Island and received at the Nauen tower near Berlin, Germany. The distance is about 3,600 miles. Heretofore it has been necessary to relay wireless messages to Berlin and other points on the European continent.

Electrification of London Railways.—The London and Northwestern and the London and Southwestern railway companies are about to carry out an important electrification scheme involving over 150 miles of track in the metropolis. Direct current at 600 volts will be employed, with third and fourth rails, the trains being operated by the multiple-unit system. The scheme includes connection with the entire underground railway system of London.

Huge Electric Clock.—To advertise the Boston Edison Company, a large electric sign has been set up in that city measuring over all 54 feet in width by 60½ in height. The sign contains a clock with the dial 34 feet in diameter, at each side of which are columns studded with electric lamps. The minute hand of the clock is 18¼ feet long and weighs 488 pounds while the hour hand is 14 feet 4 inches long, weighing 386 pounds. The total weight of the structure is 15 tons. Altogether there are 6,322 lamps used in the sign.

Curious Destruction of Fireproof Cables.—In a very serious fire which recently occurred in an English electric generating station certain cables, made with an outside covering of fireproof braid, were destroyed by fire in a remarkable way. The origin of the fire was a comparatively small blaze that had been started by an accidental short circuit. Although this first fire was promptly extinguished, it seems that the short circuit had enormously overloaded the first-mentioned cables, to the point of heating their stranded copper cores red hot. The expansion of the cores rent the fireproof braiding, exposing the rubber insulation underneath to the air so that it burst into flame.

Electrically-driven Ship Machinery.—A new English passenger and freight ship is fitted with electric motor-driven auxiliaries—one windlass, two winches, six cranes and two warping capstans—supplied with current from a central electric generating plant. The machinery was especially designed for the rapid and quiet handling of cargo, and the electric drive gives a greater over-all efficiency than steam equipment, as the prime mover is a single large unit in which the steam is used very economically compared to the waste in the ordinary "donkey engine." Furthermore, the losses in steam pipes leading to each such engine from the boilers, by radiation and leakage, are eliminated, and the equipment does not have to be "warmed up," but is always ready to run.

Wireless Telegraphy Without Ground Connection.—The new wireless telegraph station at Fremantle, Australia, which has just opened communication with Sydney, across the 2,500 mile width of the continent of Australia, is operated without a ground connection in the ordinary sense. On account of the extreme dryness of the sandy soil at Fremantle (there is absolutely no rain during the six or seven summer months, and the underground water is at a great depth below the surface) a satisfactory ground connection could not be established readily. Accordingly an insulated counterpoise is employed instead, constituting the lower element of the electrically vibrating circuit of which the antenna is the upper element. The counterpoise consists of about a hundred insulated wires radiating out from the antenna tower and joined and supported by three concentric circles of wire. The web thus formed is supported on poles which are higher toward the center and lower at the outer edge, making a flattened cone-shaped network which gives an open shape to the vibratory circuit, insuring satisfactory radiation and a more outward reflection of the waves from the counterpoise.

British Electric Welding Practice.—A recent paper on electric welding declares that resistance methods, in which the heat is generated just at the spot where it is required, alone give true welding, every other process, electrical or other, involving the fusing of the two metals together. With an alternating current transformer the current required varies according to the size and nature of the work—from 50 amperes for a small wire welder up to 73,000 amperes on a large tire welder. Resistance welding is simple, accurate, reliable, speedy, and economical in quantity production. Chain links, for example, may be welded at the rate of 10 to 15 per minute. A tire welder can average 525 tires of different sizes per week, and spot welders can make 35,000 welds per week. The thermal efficiency of electric welding is as high as 75 per cent, and the mechanical efficiency attains 93.4 per cent, which compares favorably with hand welding. Iron and mild steel can be welded very satisfactorily, though high-carbon steel (0.6 per cent carbon) does not give as good results. Copper and its alloys, nickel, aluminium, silver, gold, platinum, iridium, and brass do not lend themselves to spot welding and must be butt-welded.

Science

The Unusual Turbidity of the Atmosphere, which began last June and appears to have continued through the summer and autumn, is to be made the subject of an investigation by the U. S. Weather Bureau. A circular requesting notes of any observations that have been made of this phenomenon has been addressed by the bureau to a number of astronomers and meteorologists.

A Prize of 2,000 Marks has been awarded by the German Meteorological Society to Mr. Ernest Gold, of the British Meteorological Office, for the best discussion of the results of the international investigations of the upper air. Mr. Gold, who is only 31 years old, is probably the highest English authority on dynamic meteorology, and is one of the brilliant group of Cambridge men who have given the British meteorological service its present conspicuous position in the scientific world.

The Source of the Kongo.—A telegram from Sakania, Belgian Kongo, announces that the German officer, Lieut. Grätz, who in 1909 crossed Africa in a motor-car, has now accomplished the same feat by motor-boat. The most important geographical result of the enterprise appears to be the discovery that there is a continuous waterway from the source of the Chambezi, in northern Rhodesia, to the River Kongo, which is thus proved to be the longest river in Africa.

Sodium and the Series of Radio-active Elements.—In a recent number of *Science*, Prof. F. C. Brown discusses the evidence that sodium belongs to a radio-active series of elements. "Geophysics," he assures us, "furnishes two distinct lines of evidence which favor the hypothesis that sodium belongs to a series of radio-active elements. The first is based on the age of the earth as determined by radio-active data and by the accumulation of sodium in the ocean. The second is based on the relative accumulation in the ocean of sodium compared to chlorine, taken in connection with the relative annual output of these two elements by the rivers."

New Radio-telegraphic Stations in the Arctic.—In view of the attempts now under way to accomplish the Northeast Passage and the much-discussed question of establishing regular trade-routes by water to the Arctic coast of Siberia, great interest will be felt in both scientific and commercial circles in the announcement that the Russian government is installing radio-telegraphic stations at the entrances to the Sea of Kara, viz. at Vaigach Island, Yugor Strait and Morosola. Hereafter vessels bound for that sea will be able to lie in safe harbor at Vardo or Archangel until they are advised by wireless that the passages are free from ice.

The Plants, Animals and Birds of the Bible have been made the subject of a special exhibition in the Natural History Department of the British Museum, South Kensington, and the trustees of the museum have published an interesting "Guide" to the collection. Among the striking bits of information contained in this work are the following: The common fowl is not mentioned in the Old Testament, and was probably introduced into Palestine after the Roman conquest. The unicorn of the Old Testament was probably the Syrian aurochs, now extinct. That the "behemoth" was not the hippopotamus is made probable by the fact that there is no record of the latter animal in Syria or Palestine in historical times. The "tares" of the Bible were darnel grasses, whose seeds are poisonous, the "rose" was probably the narcissus, while the "lily" was the poppy anemone.

The Recent Progress of Actinometry is discussed by Dr. J. Maurer, president of the International Commission on Solar Radiation, in the recently published report of the last meeting of that organization held at Vienna in September, 1912. For years measurements of solar radiation were made in various parts of the world with a number of mutually incomparable instruments, including some of very little scientific value, e. g., the black-bulb thermometer. The International Meteorological Conference held at Innsbrück, 1905, recommended the universal use of the Angström pyrheliometer, and this instrument has since been employed at most large meteorological observatories, as well as in the course of special investigations, as for instance on various mountains (Monte Rosa, Sonnblick, etc.). Thus science now finds itself in possession of a fairly large body of data on the intensity of solar radiation in different parts of the world obtained by identical and approximately accurate methods, a class of information the need of which has been sorely felt in meteorology. Unfortunately, however, doubts have recently been cast upon the complete reliability of the Angström instrument especially by Kimball, in America, who finds that this instrument gradually deteriorates in accuracy. A more favorable view is taken by Marten, of the Potsdam Observatory, and among others opinion seems to be divided as to whether the Angström pyrheliometer should be retained as the standard. The silver-disk pyrheliometer of Abbot is coming into wide use. Thus the initial problem in the much-needed world-wide study of solar radiation—the selection of a satisfactory instrument—appears to be still unsolved.

Aeronautics

The Automobile Lamp and the Radiator Casing.—In patent No. 1,048,530 Don W. Harlow of Cleveland, Ohio presents an automobile radiator casing which is expanded at its opposite sides in its upper portion beyond the normal outlines of the radiator and sleeves are provided within the expanded portions to receive the lamps so that the lamps are inclosed within the radiator casing.

Another Flying-machine Patent.—In patent No. 1,049,315 Eli Pollak of Washington, D. C., assignor of one half to Edward E. Clement of Washington, D. C., shows a flying machine comprising two longitudinal cylindrical bodies which are connected at their ends to form an elongated integral rigid gas bag or envelope which has a greater width than depth and a longitudinal open space in which a car is hung, the gas bag forming an aeroplane.

Flights in Greece.—Favored by fine weather, Labouret made a number of over-sea flights near Athens and after flying in the neighborhood of Salamis he then came above the Acropolis and the Parthenon at a great height. His performances at the Piræus port were witnessed by great crowds of spectators and also by the ministers of war and the navy. In all these flights he carried two passengers on board, these being the pilots Gimnard and Bernl. The latter is proceeding to join the Epirus army with an aeroplane which he is to pilot. The Greek lieutenants Notaras and Kamberos are embarking with their Farman biplanes in order to join the same army. Lieut. Kamberos lately made some remarkable flights above the islands of the Ægean Sea upon a Farman hydro-aeroplane.

An Incendiary Bullet.—Tests have been made in Germany with a special projectile which is intended to repel dirigibles and which is designed not only to pierce a gas envelope but also to set fire to the gas. This projectile fired from the old German rifle known as "model 71," which has a caliber of 11 millimeters, is provided with little wings that open in flight under the influence of a spring, compressed while the projectile is still in the rifle barrel but expanded as soon as the muzzle is passed. An ordinary bullet leaves such a small hole in an envelope that the gas escapes through it but slowly. The wings on the improved bullet tear a hole of appreciable size in the fabric. What is more, they retard the bullet sufficiently to cause a friction device to ignite fulminate contained in the bullet. It is said that experiments conducted at Neumannswald gave encouraging results.

Another Proposed Transatlantic Flight.—The aviator Beckmann of Cologne, is preparing to make a sensational flight across the Atlantic next spring from Europe to America. He intends to start from the Da Rocha Cape in west Spain and fly across to Ferreira, the first of the Azores Islands, or 1,000 miles. From there he is to attempt the flight across the ocean to Halifax, which will mean about 1,800 miles. He will take on board 2,000 pounds of gasoline and oil, and is to fly for about 11 hours at 90 miles an hour for the Azores trip. Then he will take on 4,000 pounds of gasoline and the flight to Halifax will last 22 hours at a somewhat slower speed. This German transatlantic machine is to be a monoplane of no less than 33 feet in length and 56 feet spread, having a supporting surface of 540 square feet. The weight of the aeroplane is 1,500 pounds, and the framing is of steel tubes. It is to have two revolving-cylinder motors each driving one propeller. Wireless apparatus and search-lights will be carried on board. This may be another case where wireless will prove useful at sea.

News of Buc.—The Buc grounds near Versailles are likely to become the leading aviation center in France. Among the constructors, Esnault-Pelterie, M. Farman, H. Farman and Borel have already installed headquarters on the grounds, and at present Blériot is establishing a model aerodrome of considerable size. The work is, in fact, nearly finished, and the new quarters, built entirely of brick, comprise a main building used as an immense hangar, with two wings of two stories each. The great hall of 170 feet in length is able to house quite a number of aeroplanes, and counting the repair shops which lie at each end, the building is in reality over 300 feet long. In the wings there are installed on the ground floor the offices and a store room with extra parts for aeroplanes, besides a good-sized workshop. On the second floor are the apartments used by the pupils, workmen, guards, etc. Blériot also has dwelling quarters here so as to be able to work when need be. Adjoining the main building are two metallic hangars which already contain several aeroplanes. It is expected to have about 25 aeroplanes in use for instruction of pilots, at the start. Behind the hangars will be built the automobile sheds, and upon the main road is to be erected a monumental entry for the Blériot aerodrome which will cost $35,000 alone. The track of the aerodrome is already traced, and it will be of unusual size. It runs around the Buc fort and incloses no less than 300 acres. M. Collin, who has already trained 250 pilots in the Pau and Etampes Blériot schools, is to have charge of the aerodrome.

The Voice-operated Typewriter

ANALYZE the physical operation of taking down dictation on the typewriter. The dictator pronounces a word, say "met," and within a fraction of a second the letters "m-e-t" are struck upon the machine tremities and separated into four reeds by cutting it apart at the center. It is evident that these reeds would vibrate more or less according to the sound, just as a telephone receiver diaphragm would.

With this crude apparatus, which is shown in the accompanying photograph, the inventor has succeeded in recording on the typewriter all the vowels and the consonant "P." The consonant sounds are much more difficult to reproduce

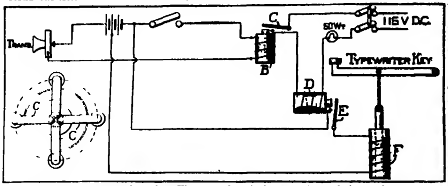

Fig. 1.—Arrangement of reeds. Fig. 2.—Electrical connections of the reed system

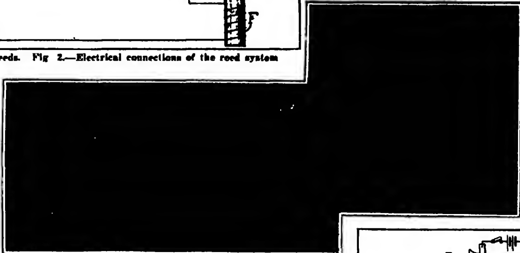
In that brief interval of time the following operation takes place:

The ear drum of the typist is set vibrating as it receives the sound waves from the dictator. Superposed upon the main sound waves are overtones of different frequency, one characteristic overtone for each letter of the word. These waves are communicated to a set of fibers in the cochlea or internal ear. There are many thousands of these fibers, each tuned to vibrate to its own individual frequency. Three of these fibers are then vibrated more strongly than the rest, one after the other to correspond with the m-e-t sounds, and the excitation of these fibers is communicated to the brain which in turn controls the muscles of the typist's fingers, causing them to strike the corresponding keys on the typewriter. No complicated mental processes need be involved in the operation. It is quite mechanical. Indeed, the typist may have been and probably was thinking of something quite foreign to the subject. But if the system is mechanical, why does not some one build a mechanical substitute for the typist, so that the dictator may control the machine by voice without a human intermediary?

Mr. John B. Flowers, a young electrical engineer of Brooklyn, has actually made the attempt and with a considerable measure of success. In his apparatus a telephone diaphragm takes the place of the human ear drum. Instead of the fibers he employs a set of steel reeds, respectively tuned to the different overtone frequencies of the alphabet; for nerves he uses electric currents, and for the human hand a bank of solenoids.

A diagram of the arrangement is shown in Fig. 2. When a word is spoken into the transmitter, the field of the electro-magnet B is varied in accordance with the sound waves impressed on the diaphragm of the transmitter. There are four electro magnets B, and each is fitted with eight reeds, but for purposes of illustration and for the sake of simplicity we have shown only one of the magnets and a single reed C. Although the reeds are tuned to different wave frequencies, they are all vibrated more or less by the variations in the field of the electro-magnet. But as each letter sound is uttered, the reed that is tuned to that particular letter vibrates more strongly than the rest and closes the circuit of the corresponding relay magnet D. This closes the switch E, actuating the solenoid F to pull down the key of the typewriter.

The electro-magnets B are virtually telephone receivers and the reeds C are their diaphragms. Fig. 1 shows how the reeds are mounted at each end of the magnet D. It is as if the diaphragm of the receiver had sectors cut out of it, leaving a cruciform diaphragm mounted on standards at the four ex-



A machine that typewrites what is spoken to it

for the reason that they are of shorter duration, and any mechanical device such as a reed would be too sluggish to respond to them. However, the inventor expects to overcome this defect by using electrical resonators in place of reeds. The arrangement is shown in Fig. 3. In this case the transmitter circuit connects inductively with the resonator mains H and I, across which are connected resonant local circuits, each comprising a balanced inductance K and capacity J. On speaking the word "met" into the transmitter, the three local resonant circuits corresponding to the letters m-e-t are successively thrown into resonance, the current rising to a high value. A small vane of some magnetic material is caused to be pulled into the center of the coil K of those circuits which are highly excited, thus closing the circuits of the solenoids F, working the keys of the typewriter. The electric resonator system has not as yet been put to a practical test, but theoretically it should be very sensitive and quite capable of catching the overtone characteristics of the consonants.

Apparently, then, all that the dictator need do is to speak into the ear of this mechanical typist and his

Architecture on the Panama Canal—A Suggestion

NO one who is familiar with our columns would question the friendly spirit in which the criticisms suggested by the two adjoining sketches at the bottom of this page is made. The character of the permanent masonry work along the Panama Canal is such that it does not admit of much architectural adornment or expression, and in view of the magnitude of the huge monolithic masses which constitute the locks, spillways, etc., we think it will be agreed that the simplicity which characterizes these works is appropriate. At the same time, in the designing of the subordinate or accessory structures, such as power houses, range towers or lighthouses for marking the course of the vessels, and the permanent buildings for housing the operating and military forces, we think that great care should be taken to render them architecturally harmonious with the spirit and purpose of this, the greatest engineering work of the day.

The range towers, of which there is a large number placed at intervals along the sailing route of the canal, are concrete structures of circular cross-section and of simple and appropriate design. In the case of one of these towers, known as front tower of range Nos. 1-2 in the Gatun Lake section, it became necessary to make a radical change of form, owing to the peculiar requirements of the site, and the result is shown in the accompanying halftone engraving which is reproduced from the last annual report of the Panama Canal Commission. The tower is situated on the south middle wall of the Gatun locks, which extends from the main structure several hundred feet out into the lake. Upon this wall are located three tracks for electric towing locomotives, one on each edge of the wall, used when the ships are in tow, and a third track to enable the locomotives to return after they have carried a ship through. In designing this range tower, it became necessary to depart from the standard circular form, since the structure had to span the central track with sufficient clearance to allow of the passing of the locomotives.

Unfortunately, the problem was treated as one merely of engineering. Four concrete pillars 20 inches by 24 inches in section were carried up the desired height, arches were thrown in, and a platform was formed above them. From the center of this relatively slight rectangular base rises the massive circular shaft of the lighthouse.

Now, although, from the engineering standpoint, this is a perfectly satisfactory structure, we must condemn

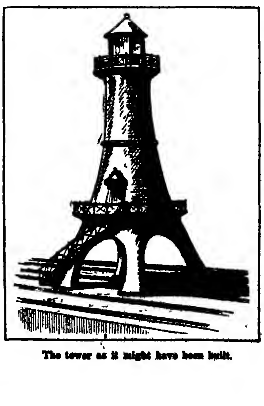
Gatun locks range tower as built.



The tower as it might have been built.

The Moreau Automatically Balanced Monoplane

M. MOREAU of Paris has been testing a monoplane which commands attention chiefly because it is provided with an automatic stabilizer He claims that he has flown thirty-five minutes without touching a lever, steering with his feet. By what the writer saw in a short flight, he believes that the feat is possible in good weather

It has provision both for automatic stability and for personal control The lateral automatic stability is secured partly by the wing shape, partly by the low placement of the mass center These are old and obvious devices which serve in favorable weather and in easy maneuvers. Longitudinal automatic stability is secured by placing the pilot in a pendulum seat shielded from the wind, movable only in a fore-and aft direction, and actuating control cords running back to the horizontal rudder This general pendulum device for automatic control has formed the basis of many patents, but as here applied has some noteworthy features presently to be indicated.

As to the mechanism for personal control, the steering is done by the feet working cords connected with a rear vertical rudder, the lateral poise is effected by ailerons operable by a special lever, the longitudinal poise is obtained by another special lever operating the horizontal rudder All these personal control devices are old and well known.

The most interesting feature of the Moreau monoplane is the combination of arrangements for longitudinal control As already stated, the rear horizontal rudder is operable automatically by the pilot's seat movable only lengthwise of the machine, and manually by a special hand lever But, furthermore, there is a brake operable either by the hand actuating a lever or by the wind acting on a pressure plate, whose function is to lock the pendulum seat so that the whole machine becomes, for the time of braking, as one rigid body Thus the aeroplane is instantly convertible from one having either manual or automatic control to one having only manual control, and in either case it has considerable inherent stability by virtue of its shape and low center of mass.

The pilot-seat pendulum of Moreau's monoplane which has also characterized the designs of other inventors, has the advantage of exerting sufficient force to work the control wires unaided by auxiliary power, whereas the light pendulum controls so frequently proposed, during the past generation or more, for automatic stabilising, require some intermediate mechanism and a special source of power, such as compressed air, or gearing driven by the motor, etc But it may be observed also that the period of vibration of the larger pendulum is longer than need be for a small one, and hence in some circumstances its action may not be quite so prompt. The ideal aeroplane pendulum would always maintain a fixed direction, or, if disturbed, would promptly and without oscillation resume its normal direction, say the vertical Like the magnetic needle, it would be unaffected by sudden shifting or acceleration of its pivot The aeroplane could then be given a definite poise with respect the normal position of its pendulum, with the assurance that the poise would in general be uniform. But the ordinary pendulum when its pivot is accelerated transversely to the line of suspension, promptly deviates from the natural plumb, to which it tends to return for repose gradually after one or more vibrations. The more frequent and prolonged these oscillations, the more unsteady the control of the machine on its course.

If for example, the aeroplane is accelerated on its path, as when starting along the earth, or when the propeller thrust suddenly increases, the pendulum tends to lag behind, thereby changing the angle of the rudder more, perhaps, than the circumstances require, if any change at all be desirable at the instant. Conversely in landing, when the propeller thrust suddenly diminishes, the pendulum swings ahead of its natural plumb position with a consequent disturbing effect on the evenness of the straight forward flight. But if a brake be available, which automatically locks the pendulum during certain extraordinary accelerations of the aeroplane, due to sudden changes of propeller thrust or sudden wind gusts, these violent movements of the pendulum and their consequent disturbing effects are obviated.

Apparently such a pendulum control should be regarded as a fair weather device. In long voyages it can relieve the pilot during much of the time even if it cannot be depended upon to save him in the most severe atmospheric conditions It may be expected therefore, that if nothing better be forthcoming, the pendulum control will win favor with some aviators, as a convenient auxiliary if not as a life preserver But it must be remarked that although practical automatic controls of various pendulum types, as well as other kinds, have been shown by their inventors to be mechanically operative, they have not made remarkable headway toward general adoption, either by operators or by manufacturers of aeroplanes. These remarks apply to pendulums of ordinary type, whether working the controls directly by their own weight or through intermediary gear involving electric clutches, compressed air cylinders, or the power of the aeroplane motor

In closing reference may be made to an automatic stabilizer governed by an extraordinary pendulum. Mr John Tarbox of Washington has pivoted a bar pendulum at its center of gravity so as to obviate disturbance due to sudden shifting or acceleration of its axis. In order to endow it with a tendency to stand plumb, one end is made bulbous and the whole is immersed in a liquid contained in a box mounted on the aeroplane The pendulum is used to operate a clutch, whereby the power of the motor may be engaged to work the control wires of the aeroplane The Tarbox stabilizer when mounted on a biplane of the Curtiss type enabled it to maintain a level poise in cross-country flying and to fly continuously round a curved course, steadily maintaining a given bank in calm air, and promptly returning to its prescribed poise when navigating disturbed air As witnessed by the writer, in 1911 it was used to control only the ailerons, but it can as well be applied to control the horizontal rudder The inventor claims for this stabilizer all the merits of those operated by common pendulums plus the additional advantage that his pendulum is unaffected in verticality by any acceleration of the aeroplane due to sudden change in the propeller thrust etc as observed for the Moreau machine The correctness of the principle of the Tarbox pendulum may be left to the intuition of the reader or as an exercise for his skill in hydromechanics. The question is Whether a pendulum pivoted at its centroid and more buoyant in its upper than in its lower part will preserve its verticality while its axis is being transversely accelerated?

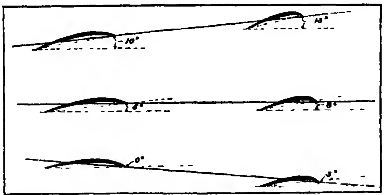
The Drzewiecki Following Surface Aeroplane With Inherent Longitudinal Stability

THIS machine is distinctly of the Langley type and it is the outcome of the various foreign machines of the Canard type originated by the Voisins several years ago, and first tried by Santos Dumont in his original aeroplane—the first heavier than air machine to fly in France The Canard type consists of a long body carrying the elevator and vertical rudder at the front end and the supporting surfaces at the rear end The aviator was placed just in front of the planes in the body and the motor was placed at the rear part of the lower plane as in the usual biplane The Drzewiecki machine, however has both surfaces of the same size and both lift about the same amount Both the men and the motor are placed in the body between the two supporting surfaces, while the propeller is located at the rear end of the body behind the second plane The center of gravity is practically at the center of the fuselage half way between the two surfaces. This is important as the position of the center of gravity influences the direction of the correcting couple when the machine tends to lose its balance, and also affects the magnitude of this couple. The machine is balanced in such a way that in ordinary flight the front surface has an angle of 8 degrees, and the rear an angle of 5 degrees There is, therefore a dihedral angle of 3 degrees between the two surfaces in a longitudinal direction The front plane has the profile curve of the No 8 Eiffel surface which gives at 8 degrees, a lift of K_y 0.058 practically while the rear plane has the profile curve of the No 13 *bis* Eiffel surface (Blériot No. 11 *bis*), which gives at 5 degrees a lift of $K_y = 0.01$ approximately Moreover, because of the difference in the two planes, the total lift of the front one varies less quickly than that of the rear when the angle of incidence changes. If therefore the machine gets out of equilibrium or in other words if the two lifts of the front and rear planes no longer balance each other with respect to the center of gravity, and the machine tends to rear the lift of the second surface increases more quickly than that of the front one and a couple is developed that tends to raise the rear of the machine and correct the increase in the angles of incidence of the two surfaces (see diagram) In the case of a dive where the angles of incidence of the two surfaces



Drzewiecki's machine rearing, on even keel, and diving, a difference of 5 degrees between each position

The Drzewiecki tandem monoplane constructed according to results of Eiffel's aerodynamic research.

diminish, the difference in lift of the two planes occurs in an opposite manner, and the greater lift of the front one brings the machine up to an even keel once more.

This principle was tried out in the Eiffel laboratory on a model one tenth the size of a full sized machine. The model was suspended at different angles of incidence and the experiments proved that it is possible to obtain longitudinal automatic stability by the arrangement of the planes shown in the diagram whereby the rear plane is set at an angle of 3 degrees less than the front one. Moreover, it has been proved by experiment that when the planes both have the same angle, the lift of the second one is practically nothing. If the second plane is given 5 degrees less angle than the front one there is no lift at all but rather a downward force. If the second plane has less angle at 2½ degrees than the front one however, the lift produced is practically the same as that of the front one so that in addition to obtaining automatic stability a lift as great or greater than that obtained with an ordinary biplane is to be had. These results were obtained experimentally by Eiffel and M. Drzewiecki constructed his machine in accordance with them. The forward wings can be turned about their axes in order to correct the lateral balance and also to increase or decrease their angle of incidence when it is desired to rise or descend. Each wing is built about a central spar that turns in a ball bearing and they can be operated separately or together by means of two levers. The twin vertical rudders on the ends of the rear wings can be turned inward across the machine at right angles with its axis, in order to form a brake when the machine makes a sudden descent. The motor used is a 70 horse-power Labor and the machine is provided with oleo-pneumatic shock absorbers so arranged that the moment the wheels strike the ground a skid is thrown downward in contact with the soil acting as a brake.

In the pages of the current SCIENTIFIC AMERICAN SUPPLEMENT will be found a discussion of the design from the aerodynamic standpoint.

New Types for the Japanese Navy

By Oscar Parkes

THE sister ships, "Kawachi," which was commissioned last year, and "Setsu," due for completion this year, are Japan's first all big gun ships to be built. Their predecessors, the "Aki" and "Satsuma" although often classed as dreadnoughts, were "intermediates" like the French "Danton" and the British "Lord Nelson" types, as they carried a main armament of four 12-inch and twelve 10-inch guns. The "Kawachi" is the normal development of these ships, and in general design seems an enlarged "Kaiori" with 12-inch guns replacing the 10-inch ones at the four corners of the superstructures, her twelve big guns being distributed after the earlier German fashion, now discarded in that and other navies in favor of the center line arrangement. The "Kawachi" displaces some 20 750 tons, her dimensions being: Length over all 481 feet, beam, 80 feet and maximum draught 28¼ feet. As originally designed she was to have carried fourteen 12-inch guns, with triple turret fore and aft and four twin positions amidships, but this was modified in the earlier stages of construction to twelve guns, twin turrets replacing the triple.

Her secondary battery of ten 6-inch pieces is disposed along the main deck, the end guns being recessed to secure axial fire. The 4.7 guns are mounted at the extreme bow and stern and in the superstructures. Five submerged torpedo tubes are carried, two bearing on each broadside and one astern. These fire the 18-inch Whitehead weapon.

Her protection consists of the usual complete Japanese belt 12-inch amidships, tapering to 5-inch at the bow and stern which reaches to the lower deck. Above this is a 6-inch strake amidships, reaching to the battery deck, and here the guns are behind 6-inch armor. A 3-inch armor deck incloses the engines and vitals. All the big gun turrets are 9 inches thick and are reported to have 12-inch bases.

Both ships are turbine driven the "Kawachi" having Curtis engines and the "Setsu" Parsons. Steam is generated in Miyabara boilers of standard Japanese pattern and the designed horse-power of 25,500 is expected to produce a speed of over 20 knots. The coal supply is 1000 tons normal and 2,500 maximum.

From our illustrations it will be seen that the ships present a somewhat unique appearance owing to the peculiar funnel spacing and the two tripod masts of British pattern. The "Kawachi" was laid down at Kure in January 1909 and the "Setsu" at Yokosuka in April of the same year but owing to financial reasons the last named will not be completed until some time in 1913.

The battle-cruiser "Kongo" is one of a class of four ships of 27 500 tons displacement, and is under construction at the Vickers yard, England. Her dimensions are: Length, 704 feet, beam, 92 feet, and draught, 27½ feet, and she carries an armament of eight 14-inch and sixteen 6-inch guns.

The big guns weigh 80 tons and are 45 calibers long. They are mounted four forward and four aft, the second and third turrets being raised "Michigan" fashion to allow an axial fire of four, and a broadside of eight guns. Along the upper deck are the 6-inch guns, and on the turret tops and upper works are distributed sixteen smaller quick fire pieces.

Official details of the armor and protection are lacking, but reliable information gives the belt as 10-inch amidships, tapering fore and aft and terminating some distance short of the extremities.

Beneath this is an auxiliary belt which is very deep, protecting the ship against under-water attack. Above is a 7-inch strake extending from the first to the fourth turret bases, and the battery is behind 6-inch armor. The protective deck is 2 inches thick.

Her 14-inch guns are in 9¾ inch turrets with armored bases of unknown but probably similar, thickness. Driven by Parsons turbines of 60,000 nominal horse-power the "Kongo" has a designed speed of 25 knots, but 27 knots is expected of her. She carries 4,000 tons of coal and 1,000 tons of oil fuel.

Of the four ships, the "Kongo" was laid down in January, 1911, and is to be completed early in 1913. The "Haruna" (Curtis turbines), "Kirishima" and "Hiyei" are all building in Japan, and are due for completion between 1914 and 1916.

Dussaud's "Cold Light"

REPORTS of the experiments that M. Dussaud, a French savant, has been carrying on since 1909 at his "Cold Light Laboratory," have occasionally filtered into the newspaper columns. These reports, although as a rule exaggerated and perverted, have created considerable curiosity about Dussaud and his work. While the discoveries he has made will not "revolutionize electric lighting," as one recent press story predicted, the truth remains that he has applied some old principles to newly and ingeniously devised lighting apparatus, and has conceived some really startling applications for the latter. On three occasions communications by Dussaud have been presented to that august body, the French Academy of Sciences, by Prof. Branly of wireless telegraph fame.

Dussaud's apparatus, in its most typical form, consists essentially of the following parts.

1. A disk or wheel, with suitable mechanism for revolving it.

2. A number of tungsten filament lamps (usually 16 of them) spaced uniformly around the rim of the wheel. The lamps have small, closely coiled filaments, the whole filament structure in a single lamp occupying only 10 cubic millimeters, whereas the filament of an ordinary tungsten lamp encompasses a space some 2,000 times as great. The bulbs are small and round similar to those commonly used in automobile headlights. A battery or low voltage dynamo or transformer supplies the current.

3. A commutator, keyed to the shaft of the wheel which causes each lamp successively to be lighted, for about 1/20 of a second only, as it passes a certain fixed point near the periphery of the wheel.

4. A projecting lens so designed and placed as to receive the light rays from the lamps, as each in turn passes by the fixed point where it is lighted.

For most purposes (moving picture machine work for example) the wheel is revolved at a speed of 16 or more revolutions per second, so that the optical effect, due to persistence of vision, is that of a single steady continuous light emanating from a point. For other purposes, as for example, in light house beacons, the wheel is revolved more slowly, so that the light is seen to be a succession of flashes.

M. Dussaud finds it possible, by making the apparatus of little inertia and using special mechanism, to stop the wheel during the twentieth of a second or so that each lamp is alight, so that the filament, while lighted, remains stationary at the exact focus of the lens. In the case of lamps with fairly large bulbs, when necessary he mounts the filament off center, thus bringing it near enough to the inclosing glass of the bulb for the little incandescent coil to be in focus.

There may seem to be nothing startling in all this, but now comes the spectacular part of the performance. Using the apparatus above described, Dussaud finds that *more than twice* their normal voltage can be impressed on the lamps, yet they will last for several hours, while the light is obtained at an economy of electrical energy absolutely unknown with any other illuminating device using incandescent lamps. Thus, by doubling the impressed voltage, a lamp normally requiring 1 watt per candle-power is made to deliver light at an efficiency of 0.3 W. P. C.! He actually impresses 2½ times the normal voltage in certain applications of the apparatus, such as medical examinations of interior parts of the body, and thereby raises the efficiency to 0.1 watt per candle, making a light twice as efficient as that of the yellow flaming arc.

While the efficiency is increased by "overvolting," the candle-power obtainable from a given bulb is increased in still greater proportion. Thus a 200 per cent of normal voltage, a ten candle-power lamp, with a bulb less than two inches in diameter, emits a light of over 140 candles.

There are two advantages in Dussaud's scheme of using several lamps in rapid rotation, rather than a single lamp continuously. In the first place, the life of each filament is increased about twenty fold, since it is in commission only one twentieth of the time. Secondly, the bulbs do not have a chance to get hot, a fact of great importance when they are used close up to moving-picture films or expensive lenses. Thus the light is a "cold light" in a double sense, very little heat is evolved in proportion to the light delivered, and even that little is so thoroughly dissipated that the apparatus remains cool.

The light intensity in a given direction may, of course, be increased by the use of a reflector in addition to the concentrating lens. Dussaud has two forms of apparatus employing reflectors, in one form the reflectors are rigidly attached to the lamps on the wheel, and revolve with it, in the other form there is a single fixed reflector mounted coaxially with the concentrating lens.

The distinguishing principle of Dussaud's "cold light" may best be stated in his own words.

"This method dissipates the objectionable *heating effect* of the electric current over a *maximum surface* where it offers no inconvenience, and concentrates the useful *luminous effect* on the minimum surface where it is needed."

With a consumption of only 160 watts of electrical energy—which will not produce even the smallest commercial arc light—Dussaud's apparatus produces results in projection work that would be impracticable with even the largest arcs manufactured.

The *applications* that Dussaud has discovered for his invention have done more to bring it into public notice than has the mere fact that the light is surpassingly efficient and intense. And the man is no dreamer. Already he has induced the French Minister of Instruction to give the "cold light" a thorough try-out in the public schools in connection with educational moving pictures exhibitions, while the Minister of War is considering its applicability to military search lights.

Owing to the comparatively high expense of bulb renewals with the Dussaud system, as well as the necessity of moving parts, one is inclined to view with incredulity any claims that it will ever find much favor as a general illuminant, although the inventor rather naively suggests that it may be used with hollow inverted reflectors to produce beautiful indirect lighting effects in drawing rooms, conservatories, etc. Its province seems rather to embrace several specialized applications of electric lighting, to the development of which he is wisely confining his attention.

Among these special applications is that of endoscopy or examinations of the internal organs of the body. So intense is the light that, when it is placed under the hand the finger bones and principal blood vessels are clearly seen. In many cases it is believed that this powerful, cold light will enable bullets and other foreign substances to be located without the necessity of an X-ray examination. Letters can be read, it is said, even when wrapped in a dozen thicknesses of note paper and inclosed in an envelope.

A second application, already mentioned, is that of cinematography. Dussaud claims that his apparatus will do away with the cumbrous moving picture machines and asbestos-lined cabinets now in use. No shutter will be necessary to cover the lens during the interval of 1/64 of a second between two successive pictures, for that can be taken care of by the commutator, which causes the incandescent lamp to be extinguished during that interval. Moreover, the present commercial dimensions of the positives, 8½ × 10 centimeters, can be reduced to 19 × 24 millimeters, owing to the possibility of using lenses of shorter focus, in fact, the "pocket moving picture machine" is seen as an imminent possibility. The cost of the lamp bulbs with the Dussaud machine is about equal to the cost of current with an arc, but a considerable saving is said to result on account of the smaller investment with the former.

Paradoxically, the Dussaud "cold light" is produced at an unusually high filament temperature; indeed it is that very fact that makes the "cold light" possible. As high-temperature radiation is rich in the shorter wave lengths (blue, green, violet, ultra violet) which are chemically the most active, it follows that the new light is a good one for photographic purposes, such as the making of silver prints. For flash-light photography it can be used on many occasions when magnesium powder would be considered a nuisance.

M. Dussaud is experimenting with a "cold light" machine in which the lamps and optical system are of quartz instead of glass, in order that the chemical and pathological effects of the ultra-violet rays may be studied.

Recent reports indicate that Dussaud's "concentrated cold light" has another field of practical usefulness in light-house beacons.

Shall We Build Battle Cruisers?

Every Big-gun Cruiser Would Mean One Less Battleship in the Fighting Line

By R. D. Gatewood, Naval Constructor United States Navy

1. There can be no doubt that there are many adherents of the new and very interesting type of ships that has recently come into being, variously termed "battle-cruisers," "cruiser-battleships," and "high-speed-battleships," and that there is considerable criticism of our Navy Department, both in this country and abroad, for not building them It would be difficult to say whether this be due to the fact that other powers have them and we have not, or that the type with its greater size and speed, and its powerful guns, appeals to the popular mind, or that we really do need them.

2 Involving as it would a change of policy and a very large expenditure of money, let us consider the matter from every viewpoint before answering the question that forms the title of this article.

Type

3 These vessels first came into being in 1906 with the British "Indomitable" class. To-day both England and Germany have battle-cruisers in considerable numbers, and are building more. Japan is building four We, however, have none nor are any yet projected.

4 Battle-cruisers differ from contemporary battleships in three main factors

(1) Greatly superior speed

(2) Slightly inferior battery

(3) Greatly less protection.

An examination of Tables I and II taken from Jane will make this quite clear It will be noticed that while the standard battleship speed stands at about twenty-one (21) knots, the battle-cruiser speeds are from thirty (30) to forty (40) per cent higher The size of guns in both types is the same but the cruisers carry fewer of them. The armor belt, which is nine inches on the latest British and German ships, is not only much less in thickness, but is spread over a less area and is tapered more at the ends than is the case with battleships.

5 Future battle-cruisers will almost certainly maintain these differences, and any that we design will in all probability be built to have a radius of action greater than those of other countries, since our strategic position is such as to require this. If we adopt this type, we may therefore expect to have even bigger and more costly ships than any other nation. Assuming that we decide to build such vessels with a speed of thirty (30) knots, an armor belt of eleven (11) inch thickness, eight (8) 14-inch guns, and a radius of action of eight thousand (8,000) miles, a fair estimate of the cost of a single vessel would be twenty million dollars ($20,000,000), and this, of course does not include the large incidental expenditure involved in deepening channels and enlarging docks which would be necessary

6 To be of any real use, either tactically or strategically, at least four of such ships, or one division should be authorized, and not a single unit Just here it is interesting to reflect that any vessel appropriated for in 1913 could not join the fleet before 1916. At that time, assuming that we build two capital ships per year from now on, the situation will be

	Japan	Germany	United States.
Battleships	6*	17	11
Battle-cruisers	7	8	0
Battleships, Second class	13	12	24

Thus, even if two battle-cruisers should be added to our fleet by 1916, they would be opposed to eight similar cruisers of Germany, or seven of Japan, and it is difficult to see how so small a number could accomplish anything.

Uses.

7. In considering now the uses to which this type may be put we naturally consider them under the three heads: (1) Before action. (2) In action. (3) After action.

(a) *Before Action.*—There is no question that they would be very valuable for quickly reaching a sea out let, or occupying an advanced position of importance or relieving a threatened base, or re-enforcing another fleet in a given time all of them rôles requiring high speed as well as offensive power

They would be useful as scouts but here several things are likely to be overlooked. In the first place, the maximum speed of one of these cruisers cannot long be maintained on account of the excessive coal consumption. At full speed, they will probably burn the equivalent of one thousand (1 000) tons of coal per day Also it is very questionable whether any commander in-chief would care to detach far from his battleships vessels that could deliver such powerful blows in the fighting line Then, too, for anything but distant scouting the aeroplane is undoubtedly going to be superior to any ship. The strong claim made for

battle-cruisers for this short range scouting is that, when used in a screen, they can drive in the scouts of the enemy and prevent them from getting valuable information, and they may even be able to force an action where the enemy is unwilling to engage

(b) *In Action.*—When the action is actually joined they would be very useful in obtaining a position at the head of the enemy's column, opposing his weak end on fire with their powerful broadside fire and thus 'capping' his column, as it is called, and forcing him to change his course. Or they might be used in the much talked of, but never used, formation of the "fast wing," which is simply a detached body available for threatening the head or rear of the enemy's column or a weak point in his line.

(c) *After Action.*—Assuming that these cruisers have preserved their speed after the battle which on account of their light armor could probably only be done by keeping them out of it, there could be no doubt that they would be of great value in the pursuit of a damaged and retreating enemy either in heading him off harassing his flanks, or in reinforcing pursuing destroyers.

8 The above is an outline of the probable uses that would be made of this type by the powers possessing them. Should we attempt any of them, however it will be at once seen that against any probable enemy we will be hopelessly outnumbered. Also, in all the great naval battles at Aboukir, Trafalgar Lissa, Yalu Manila, Santiago, and Tsushima, there has always been a very decided attempt to force the issue of the action in the shortest possible time by massing the attack of all possible units, and I believe that in the last analysis, any such cruisers as we might construct would, of necessity, operate in the line of battleships.[*]

Conclusions.

9 England is building this type because she already has an extremely powerful navy in conjunction with which they can be used to the best advantage and also because she needs them to protect her rich and widely separated colonies. Germany is building them because England is, and because she seems able to afford both battle-cruisers and battleships at the same time Just why Japan is building them at the expense of battleships is indeed difficult to see, but that country has four powerful battle-cruisers of the Kongo type, as illustrated on the front page of this issue

10 For the United States it must be clearly understood that such cruisers could only be constructed at the expense of battleships. We cannot have both and from the above it is seen that we cannot have the cruisers without a very great expenditure direct and incidental Under no circumstances should we jeopardize our chances of keeping our battleship fleet up to an adequate standard, and until we can maintain that, the battle-cruiser is a luxury that we can ill afford

The Technical Experiment Station of Vienna

WE have received the following communication from the Technical Station of Vienna

"This station plans to prepare a directory of all technical experiment stations at home and abroad

"For our records we require the following data

Statement of the special field covered by the experiment station address, name of owner, director and employees, date of erection, furthermore statement as to whether the institute is independent, or is connected with an institution for technical instruction, or with a factory company or other industrial enterprise, whether the institute is open to the general public, or has been installed only for private practice lastly, details regarding the installation and size of the institute

All technical testing stations, except ing those who have already communicated with the undersigned are, therefore requested kindly to make early response to this inquiry

"The Imperial Testing Office is also prepared to receive information regarding new developments and departures in the field of technical testing

"THE IMPERIAL AND ROYAL TESTING OFFICE,
January, 1913 EXNER, *President*."

Using Ice to Save Apple Trees

A MARYLAND orchardist has found that the balmy spring like weather prevalent this winter in some sections of Maryland promises to cause a premature blossoming and budding of his apple trees, and is said to have purchased a hundred tons of ice and cracked or broken the same into small pieces which he has packed about the roots of the trees to produce in this manner a temperature which will retard the blossoming of the trees It is a common expedient to heat orchards to prevent injury by frost, but this is believed to be the first instance where artificial cooling has been resorted to The orchardist declares that if the warm weather continues, the apple and peach crop in his section will be considerably reduced if not entirely destroyed unless some means are resorted to to prevent the premature blossoming.

[*] In this connection it is interesting to note that the official name recently given to these cruisers in Germany is Linienschiff Kreuzer, or cruisers of the line.

Photographing from a Skyrocket

IT takes an active imagination, surely, to see any sympathetic relationship between a skyrocket and a camera—so delicate is the one, so boisterous the other, but the feat was not beyond the powers of Mr Alfred Maul, who has linked the one to the other in a happy co-partnership the results of which are shown in the accompanying excellent photograph taken by his device

The rocket-camera as it might be called, was designed for military purposes and was demonstrated before the German military authorities with such success that it has been officially accepted. The problem was not an easy one and the inventor claims to have been trying to yoke up these two very dissimilar things for some twelve years, for it has taken that time to bring the device to its present undoubted perfection

The accompanying illustrations, for which we are indebted to the *Illustrated London News*, show the construction of the camera-carrying rocket, the method of mounting and firing it, and the way in which it is knocked down and packed on a light handcart for transportation The apparatus is described as consisting of a camera held in a pointed hood, at the top of which is a pneumatic electric contact, and a holder which contains a parachute and the upper part of the rocket. On the top of the holder is a gyroscope which serves to maintain the camera in the desired position for the snapshot The stick of the rocket is about fifteen feet in length, and it is fitted at its lower end with wooden feathers. The whole rocket is twenty feet in length and it weighs about eighty four pounds. The camera is capable of taking eight by ten inch plates.

For giving the proper direction in firing the rocket is mounted in a special form of 'gun-carriage' which is mounted at the apex of a stout triangular base and is capable of being elevated through any range from the horizontal to ninety degrees. When the rocket is fired electrically (from a distance of about 200 yards) the gyroscope is started, and, in about eight seconds' time the rocket with the camera reaches a height of about 2000 feet When the rocket is turning at the highest point of its trajectory the camera being held in the proper direction, covering the field of view, by the gyroscope the camera shutter is released and the photograph is taken At the same moment a parachute, which forms part of the apparatus in the head of the rocket, is set free and the rocket divides into two parts The parachute opens and the whole of the mechanism rocket head, etc drops gently to the ground landing in about fifteen minutes. We reproduce some of the photographs which have been taken with this instrument, and they are so sharp and clear in definition, that they could not fail to give valuable information regarding the strength and disposition of the enemy's troops, artillery and earth works.

ROCKET PHOTOGRAPHY

The Enlargement of the Aswan Dam

By the English Correspondent of the Scientific American

THAT great engineering work, second only in magnitude to the original construction, the enlargement of the Aswan barrage across the Nile, has been completed. The work has been in progress for nearly six years, and although of a somewhat delicate character, it has been carried through to completion without a single untoward incident.

When this barrage was first contemplated Sir William Willcocks, the eminent irrigating engineer, recommended that the great wall across the river, 1 21 miles in length, should be of sufficient height to impound the water to a level of 114 meters (380) feet above sea level, the maximum head of water thus obtained being 26 meters (86 feet), whereby the volume of water stored would amount to 88,300,000,000 cubic feet in round numbers. This seems an enormous volume, but it was only a little more than fifty per cent of that actually required to meet the needs of the country which could be served.

Unfortunately, public opinion demanded the reduction in the height of the barrage, and the Egyptian government responded to the popular outcry However, the amended work was designed in such a manner that, if the exigencies arose, the wall might be heightened by 6 meters (20 feet) with perfect safety

After the barrage was opened and the widespread benefits that were bestowed by the scheme became recognised, the mistake in reducing the height of the structure was appreciated. The question as to whether a greater volume of water might not be impounded by raising the crest of the barrage was discussed. Sir Benjamin Baker stated that such an end could be achieved with complete safety, if carried out upon the lines he laid down He prepared the plans for the alterations, which involved increasing the height of the barrage by 5 meters (16.6 feet) and augmenting its thickness also by 5 meters. In this way the water level would be raised by 7 meters (23.4 feet), whereby the volume of stored water would be increased from 35,800,000,000 to about 81,200,000,000 cubic feet

The contract, which was estimated at $7,500,000, was handed over to the well-known British contractors, Sir John Aird & Company, who had been responsible for the original works, and to whom we are indebted for the permission to describe and illustrate the alterations. The important problem was the bonding of the new with the old work Sir Benjamin Baker recommended that, in building up the new part of the masonry, a space ranging from 2 to 6 inches should be left until sufficient time had passed to enable the temperature of the old and new masses to become equal, when they were to be connected by cement grouting.

Accordingly, the new work was built up in front of the old, and was not connected to the latter except by a number of steel rods of 1¼ inch diameter and 8 feet in length, sunk to a depth of 4 feet into the old work, and disposed at intervals of about 3 feet 6 inches. Extreme care had to be exercised to keep out moisture, and also to prevent débris from falling and collecting in the space between the two sections.

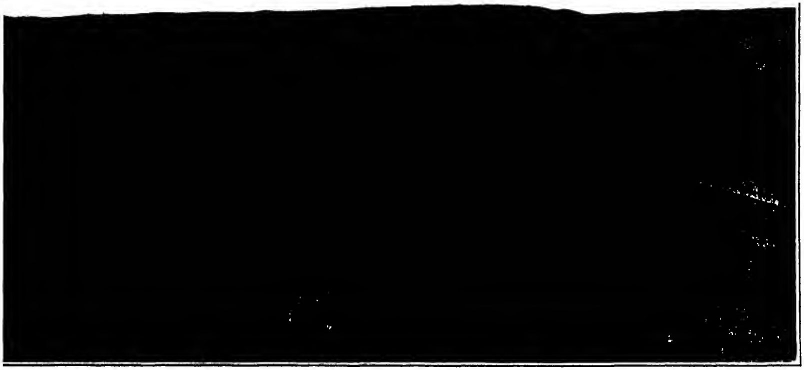
The work of attaching the new masonry to the sloping face of the dam had to be carried out during the periods when the sluices were shut, temporary embankments being improvised with bags of sand to keep the working area dry The work was done in separate sections, and as it was spread over five seasons, adequate time was offered before the new and old parts of the work were connected by the grouting. Owing to the careful arrangements made by the contractors in regard to labor, the programme, carefully prepared before the work was started, was carried out exactly as planned, and the new parts of the wall stood fully two years before the connecting bonding was taken in hand.

On the western side the barrage terminates in the structure forming the navigation lock. Formerly there were four lifts to meet requirements when the water was impounded, but in the new work a fifth lift had to be added. So far as the locks are concerned the walls of each have had to be raised, the extent of this increase varying from 18.4 feet in the case of the upper lock to 19.7 feet in the case of the fourth lock.

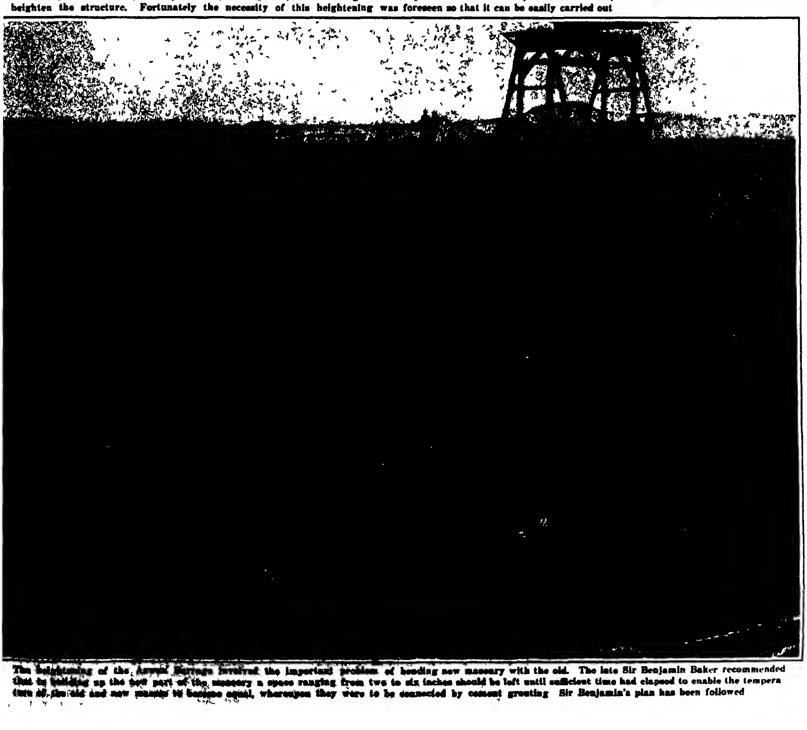
The alterations demanded extensive rearrangements in connection with the lock gates. These, as was pointed out in the SCIENTIFIC AMERICAN upon the opening of the original dam several years ago, are of a special single-leaf sliding type. Now, as the water level has been raised, the depth of water in the uppermost locks is very great, demanding gates 73¾ feet high, by 32 feet 2 inches wide, while the other gates are 59, 52½, 46 and 36 feet in height, respectively. Each is carried on a carriage which rolls over a roller path carried partly on a bascule and partly on the wall of the lock. On the land side a recess is provided in the wall in which the gate is carried when boats are passing through the lock.

In the alterations the gates were either moved bodily

(Concluded on page 142)



When the Aswan Barrage was first projected Sir William Willcocks recommended that its height should be great enough to impound the water to a height of 380 feet above the sea level. The enormous volume of 88,300,000,000 cubic feet which should have thus been stored up seemed so vastly in excess of the actual requirements that, in response to public opinion, a lower height was adopted. The reduction proved a mistake, and now it has been decided to heighten the structure. Fortunately the necessity of this heightening was foreseen so that it can be easily carried out



The heightening of the Aswan Barrage involved the important problem of bonding new masonry with the old. The late Sir Benjamin Baker recommended that in building up the new part of the masonry a space ranging from two to six inches should be left until sufficient time had elapsed to enable the temperature of the old and new masonry to become equal, whereupon they were to be connected by cement grouting Sir Benjamin's plan has been followed

The Altamira Wall Paintings

Some Remarkable Specimens of Primitive Man's Art

Aurochs, or European bison, 1.50 meters from nose to root of tail.

THE originals of the eight animal drawings reproduced on this page are probably of greater interest as *documents of human history*, than anything that can be found in Egyptian tombs or pyramids. They are in fact, taken with the circumstantial evidence attaching to them our warrant for believing that artistic power was highly developed in Palaeolithic man Of the vigor and correctness of the drawings there can be no question for anyone who has what may be called the zoological eye In an article on 'Man of the Old Stone Age in *The American Museum Journal* Prof Henry F Osborn says of these paintings "The frescoed ceiling of Altamira is the finest expression of palaeolithic art Not even the faultless reproduction of Abbé Breuil can convey any idea of the impression produced by this wonderful chamber It ranks for palaeolithic times with the great gallery of Velásquez in the Prado of Madrid The date of these paintings has now been determined—roughly at least—as between two hundred and three hundred centuries ago, in days when European man lived in caves and ate the flesh of the aurochs, or European bison

Between that remote period and the day—about thirty years ago—when Don Marcelino Sautuola first had his attention called, by his little daughter to the figure of an aurochs on the wall of the Altamira cavern these works of art had probably been seen by no human eye They are only dimly visible by the scanty daylight which falls upon them Don Marcelino was busy digging for flint implements in the floor of the cavern and unearthing bones which might tell him what the prehistoric tenants of the cave were in the habit of eating, when his little daughter, pointing at the wall suddenly exclaimed, 'Toro' Then by the light of candles, they began the investigation of these pictures which have since become famous, more particularly through the great monograph (*La Caverne d'Altamira*) published by M Emile Cartailhac and the Abbé Henri Breuil

But fame did not come to the Altamira cavern immediately after Don Marcelino's discovery After an examination by M Harlé, it seemed that the thinness of the crust of lime which coated the pictures indicated a comparatively recent origin, and their true palaeontological significance might have been lost had it not been for other wall paintings found in other caves, which carried with them—in the fact that the subjects included palaeolithic animals, such as mammoths evidence of extreme antiquity Altamira is in the neighborhood of Santillana, in the Asturian province of Santander which lies to the south and west of the Pyrenees. North and east of the same range investigations at several other places brought to light other drawings of animals, notably those of La Mouthe (1895) and *Combarelles* (1901) The increased interest in prehistoric cave pictures, leading to comparison of all these discoveries, and study of the remains found on the smoke-blackened hearths ended in the conclusion that Altamira as well as its French counterparts was indeed a palaeolithic dwelling

One of the first difficulties in the way of accounting for these paintings was the absence of daylight upon the surfaces which they adorn Palaeolithic man, presumably could not paint in the dark, or even in a twilight, any more than modern man But modern

Bellowing aurochs painted over unfinished sketch of one charging

Boar, 1 45 meters long from snout to tail. The artist began his sketch with one pose and finished with another

Galloping boar, 1 60 meters from root of tail to snout.

man—Don Marcelino Sautuola and those who followed him—needed good modern candles to obtain a good view of the pictures, and they had some difficulty in keeping the smoke of their candles from blackening the painted walls, just as the smoke of palaeolithic kitchen fires had left its mark to endure for more than twenty thousand years. It was only after a study of the remains of utensils found in the caverns that the *savants* solved this difficulty by the hypothesis that the prehistoric artists used lamps consuming animal oils, somewhat analogous to the blubber lamps of the Eskimo. Such lamps would give a very clear light, with hardly any smoke There remains the question Why should the primitive *artists* have chosen to decorate the darker recesses of their dwellings, rather than practise their art where the light of the sun would have helped them?

The answer to this question is connected with certain features in the wall paintings which at first were in themselves much in need of explanation In the first place, the various figures are not arranged in the form of friezes, or in any other way which would indicate that their intention was decorative they are placed here and there without any apparent artistic design whatever, though some of them are so drawn as to utilize accidental unevennesses of surface, giving something like an effect of colored reliefs. Then again, the figures are sometimes surrounded by lines of conventional indications which have been interpreted as representing little primitive houses. Putting all these circumstances together It seems probable that the paintings were made not for the love of beauty, or to 'show the hand' of palaeolithic Giottos, but with strictly business aims. They were, in fact, primitive pot boilers, done to supply the larder with material In none of the caves is there a picture of any animal that was not eatable, and—by the evidence of the bones found on the hearth—actually eaten by the cave-dwellers. The same, it appears, is true of the animal pictures made by Australian aborigines. The hypothesis of M Salamon Reinach is that, like the Australian aborigine, the palaeolithic man of Southern Gaul and Northern Spain believed in his own paintings of deer, boars, aurochs, horses (considered good eating) and mammoths as potent to attract the animals themselves. The pictures were supposed to operate as charms on the very big game which they represented, so that these creatures found themselves instinctively wandering into the vicinity of the cavern adorned with their effigies, and the farther in the pictures were, the more secure would be the capture of the subjects.

As to the primitive apparatus with which these paintings were achieved, the learned investigators have reached some important conclusions. Whatever may have been the material of the pigments, it was ground in stone mortars with stone pestles. The pigments were laid on with animal fats, instead of oils, from a palette consisting of the scapula of some animal For brushes, it is supposed that these primitive painters used the feathers of birds or sticks chewed at the ends.

Three animals an ox (finished), a horse and a boar (sketched). 2.25 meters between the extreme muzzles.

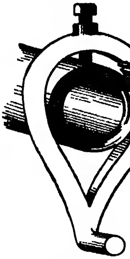
Hind, 2.20 meters long Evenness of the outlines indicate a smooth wall surface. Small aurochs to the right.

Aurochs, 1.50 meters from forehead to hind quarters. Outline formed partly by irregularities of the surface.

Notched Lathe Dog

By William Gritzinger

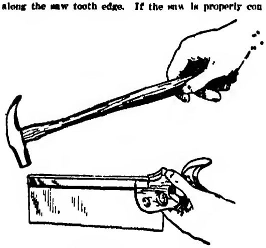
AN ordinary lathe dog can easily be prevented from letting its work slip and causing trouble. The following method will prove good. Take a three-cornered file and file several deep notches into its inner face at one side. Now put the work and dog in place as illustrated, and the dog will grip it with astonishing firmness. Work as large as the dog will admit can now be turned without slipping.



Non-slipping lathe dog

Straightening a Back Saw

AFTER the back saw has been set and filed quite a number of times it will become slack and kinky along the saw tooth edge. If the saw is properly constructed one tap of the hammer on the back at the extreme end, will straighten it instantly.—A. B.

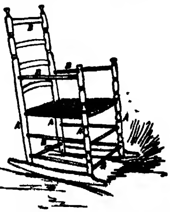


Straightening a back saw

Chair Making One Hundred Years Ago

By Albert F Bishop

QUITE frequently in occupying a very old chair it will sway from side to side quite easily, but still the parts will not separate. This is due to the construction, which is quite ingenious. The wood in shrinking grips tightly on the rounds. The uprights or legs marked *A* are of green wood. The rounds and curved back connections marked *B* are thoroughly seasoned. You can readily see that when the green wood becomes seasoned it will shrink very tightly on the seasoned pieces, so much so that they very seldom come apart, although there is no glue used.

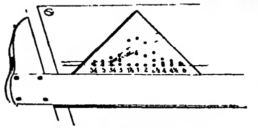


Chair construction of our great-grandfathers.

Lettering Triangle

To the Editor of the WORKSHOP DEPARTMENT:

Referring to the different suggestions for making the guide lines for lettering drawings that have appeared from time to time in your columns, I wish to call attention to a very neat device stationers are selling over here. It consists of a triangle made of celluloid and provided with vertical rows each of three flaring holes. Placing the point of a lead pencil into one of the holes of the row selected, the triangle is run along a ruler by means of the pencil point. Arrived at the end of the line thus drawn the pencil is placed into another hole of the row in question and a line drawn in the opposite direction. The operation is repeated once again and these lines will be found to be drawn exactly parallel and spaced correctly apart. The rows of holes are designated by the number of the round-writing pen best adapted for the size of letters in question.



Drawing guide lines for lettering

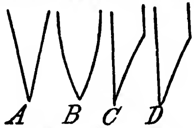
Bonn, Germany — ED. C MAGNUS.

Sharpening Edge Tools

By W D Graves

THE essential feature of a good cutting edge is that its two sides shall form a sharply defined acute angle which can only be attained by having such sides straight as shown, much magnified, at *A* in the drawing rather than curved as shown at *B*. Where the novice usually fails in whetting an edge tool is in giving it a rocking motion, producing the rounded edge and the principal element of skill in the operation lies in holding the blade and the stone at the same relative angle throughout. There are some apparent exceptions to this rule, as the common ax but they are only apparent, not real. An ax used for chopping is better ground with the sides smoothly curved but the sides of the extreme edge, if it is a good edge, must be straight. Of course these straight sides may be very short, only as long as they are made by the final setting," or whetting, of the edge, but they are there.

The proper "thickness" of the edge i e the degree of acuteness of the angle formed by the two sides depends wholly upon the nature of the tool and the work it is intended to perform. A 'thin' edge will of course, cut more easily but it will also break and become dulled more quickly, so the proper angle must be determined, by observation and experiment, for each tool and purpose. The conservative beginner will aim to err in the way of making the edge too thick, then as he finds it amply strong to do the work without breaking or nicking he will make it a little thinner and so proceed till he learns the most effective and economical angle. An edge which would be sufficiently enduring on soft pine would become almost immediately blunted on lignum vitae while, for use on any given wood, differently tempered tools require sharpening at different angles in order to give the best results.



Various forms of cutting edges.

As most wood-cutting tools are sharpened like a chisel this form of edge may perhaps best be used in illustrating the method of sharpening all. If the tool is very dull the work of sharpening is expedited by first grinding it on a stone or wheel of a grit too coarse to make the final cutting edge, taking care to have it symmetrical and either straight or of the curve of the grinding wheel, as shown at *C*. This method of making the sides inwardly curved—or 'hollow grinding'—which is carried to its extreme in razors, lessens the work of whetting, but tends to make the edge weak and incapable of withstanding hard usage.

On the grindstone or abrasive wheel the tool is brought to an edge somewhat more acute than is desired for the finished one; but, owing to the coarseness of the abrasive used, it is too rough for keen cutting. The final edge is "set" by rubbing with or on a flat finishing stone of finer grit, making a new and sharply defined bevel as shown, magnified, at *D*.

All cutting edges are somewhat serrated, some being finished on a stone so coarse that the serrations may be seen with the naked eye, as that of the common scythe. Such edges are made to cut by a sliding action, like a saw, and, for that matter, even a razor will cut much more readily if given a slight endwise motion.

Strap Hinges vs. T-Hinges

By G W D

IN deciding whether to use strap or T hinges one should keep in mind the fact that, when the two are of the same nominal size—as six inch or five-inch—and of about the same cost, the T hinge is about twice as strong as the other. A thing is only as strong as its weakest part, and the weakest part of such hinges is the joint or that part of the flap which bends around the pivot. Both strap and T hinges usually fail through the straightening out or breaking of this part and, as will be seen by reference to the accompanying sketch this part is twice as wide in the *T form* as in the strap. In the T hinge it is of the whole width of the strap as at *A B* while in the strap hinge it can be of only half that width, as *C D*.

Fig 1.—Strap hinge

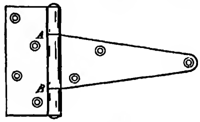


Fig 2.—T hinge

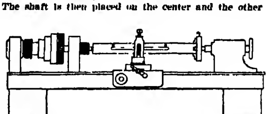
Cutting Keyways With a Lathe

By H D Chapman

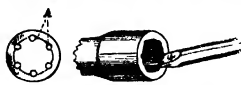
A METHOD of cutting keyways with a lathe is pictured in the accompanying drawing. A plug center is made to screw in the lathe chuck as shown at *A*. The center is then placed in the tail stock of the lathe. The shaft is then placed on the center and the other end in the chuck thus holding the shaft rigid while the keyseat is being cut. A hole is drilled at either end of the keyseat *BB*. This gives the tool clearance while it is being machined. The lathe is geared up to a high pitch the tool is set in the tool post the lathe is started up, and the feed is then thrown in thus feeding the carriage along the work. Of course a special tool is required to suit the keyseat. A keyseat can be cut in a lathe just as well as it could be in a shaper.



Cutting keyways with a lathe.

Making a Socket Wrench

MOST mechanics will not take the trouble to cut out a socket wrench but this is easy enough when done according to the drawing. It is laid out on the steel for drilling. Six small holes should be drilled if the socket is to be a hexagon. These holes will cut out the corners. Then one large hole is drilled in the center which will cut out nearly all the stock and should cut two thirds of its way into the small holes. Then there is but little chipping to be done after this operation, simply two small fragments, which are indicated at *A*.



Method of cutting out a socket wrench

Recent Improvements in Machine Tools—I

[IT has often been said and rightly so, that the perfection to which metal working has attained is one of the miracles of modern times. In many factories throughout the country the various pieces are turned, milled, sawed, planed, or ground in such quantities at such speeds and with such unfailing accuracy as to command the admiration of the observer. Yet in spite of this perfection there always seems to be room for further improvement. This is the first of a series of brief articles on recent improvements that have been made in machine tools.—EDITOR.]

AMONG the inventors who have recently added valuable changes to the highly developed art of machine tool manufacturers are F. L. Eberhardt and W. F. Zimmermann of Newark, N. J.

The device patented by these inventors is a machine for cutting the teeth of helical gear wheels, without imparting a differential motion either to the blank to be cut or to the cutter.

The advantage of this invention lies in the fact that a single direct connection is established between the rotation of the cutter and blank spindle, an advantage which is an essential feature in all generating mechanisms. A more perfect control of the feeding mechanism, both of the cutter and of the blank itself as well as of the relative ratios of rotation of the cutter and blank, is thus effected.

In the figures, the work table 3, adjustably mounted upon the frame 1, is provided with a revoluble work spindle 4 in which the work arbor 5 is secured, whereby the gear blank 8 is centered and secured in the spindle 4. A worm wheel 7 is fastened in the lower end of the work spindle 4 and rotated by the worm 8 in engagement therewith. This worm is mounted in the bearings 9 of the work slide 3, and is provided with a gear 10 which meshes with a gear 11 slidably keyed to the index shaft 12.

The index shaft 12 mounted in bearings at either end of the frame 1, is connected to the index driving shaft 13 by means of a compound train of change wheels 14, 15, 18, and 19 to drive the feed of the helical cutter 31. The stud 16, carrying the gears 15 and 18, is slidably arranged in the arm 17 to accommodate change gears of different diameters. This arm 17 is pivotally mounted upon the driving shaft 13, and is secured in the various positions by the bolts 22 to the bearing 21.

The drive shaft 13, which imparts motion directly to the gear blank receives its motion from the main shaft 25 (Figs. 2 and 3) rotated by the cone pulley 28 through the worm wheel 26 and the worm 27. The ratio of the worm wheel 26 and worm 27 must be equal to or a factor of the ratio between the main driving shaft 25 and the helical cutter so that for each rotation of the cutter the index drive shaft will make a complete rotation or a multiple thereof.

The helical cutter 31 is secured to the cutter shaft 32, mounted to rotate in the swivel carriage 33. The cutter carriage 34 upon which the swivel carriage 33 is mounted is vertically adjustable upon the stanchion 2 and is parallel to the axis of the gear blank. The swivel carriage 33 is secured to the cutter carriage 34 in any angular position in relation to the gear blank by bolts 35 in the T slot 36.

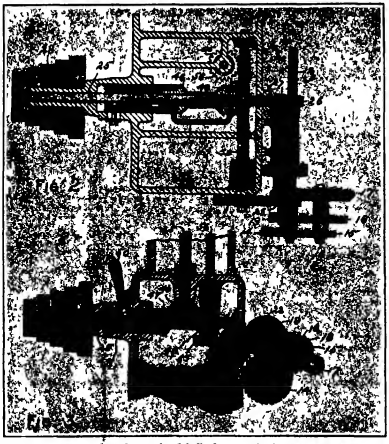
The helical cutter is pivoted about the shaft 12 by means of the bolts 35 and T slot 36, and a rotatable connection through the driving gear 37, pinion 38, shaft 39, bevel gears 40, 41, 43 and 44 is thus secured with the cutter drive shaft 45 for any angular position of the cutter.

For reversing the direction of rotation of the helical cutter, the bevel gears 47 and 48 on the drive shaft 25 are operated by the yoke 49 and handle 50 to engage, alternately the bevel gear 46 on the cutter drive shaft 45.

The feed of the cutter parallel to the axis of the gear blank is obtained through the change gears 23 and 24, feed worm gears are selected in accordance with the material of the blank and the angle of the helices and placed in position. The proper index change gears are next placed between the index driving and index shafts. The work blank is then adjusted by the screw 58 and the hand wheel 59 for the proper depth to be cut.

The teeth of the gear will then be cut

A single direct connection is established between the rotation of the cutter and blank spindle, an advantage which is an essential feature in all generating mechanisms.



A machine for cutting the teeth of helical gear wheels without imparting a differential motion either to the blank to be cut or to the cutter.

shaft 53, feed worm 54 and wheel 55, from the index driving shaft 13, which rotates in synchronism with the helical cutter. The feed screw 56 engages a threaded portion 57 of the cutter carriage 34 and is rotated by the feed worm wheel 55.

To arrange the apparatus to cut helical gear wheels with a helical cutter, the gear blank is mounted upon and secured to the work spindle, the cutter is secured to the cutter spindle, and the swivel carriage is adjusted to the proper angle with relation to the gear and according to the angle of helices to be cut, and is secured in such position by bolts. The change feed by one passage of the cutter across the face of the blank.

(To be continued.)

Prizes Offered by German Engineering Societies

THE Verein Deutscher Maschinen-Ingenieure offers a number of prizes, as follows:

I. A prize of 1,500 Marks for an investigation of the causes and means of prevention of street noises due to railways and street railways.

II. A prize of 1,500 Marks for a thesis on modern systems of steam heating for railway carriages.

III. A prize of 1,500 Marks for a thesis on modern lifting devices in use in locomotive works.

IV. A prize ranging up to 4,000 Marks for the design and computation of springs for railway carriages.

Readers interested in these competitions are advised to address further inquiries regarding details and conditions to Die Geschäfts stelle des Vereins Deutscher Maschinen-Ingenieure, Lindenstrasse 80, Berlin, S. W.

COMPETITION FOR MINER'S ELECTRIC SAFETY LAMPS.

According to *Electrical Engineering*, a prize of $6,250 for the best electric lamp provided with a reliable fire-damp indicator is being offered for competition in Germany by the Verein für die Bergbaulichen Dortmund. The lamp is to be capable of giving a light of one Hefner candlepower after burning for 12 hours, must be safe in the presence of fire-damp even if damaged. Three lamps with descriptions (in German), drawings, etc., in triplicate, must be submitted to the Verein, at Essen-Ruhr, before October 1st, 1913. The judges will be a committee representing the Government, the Westphalian Miner's Association, and the Dortmund Mine Owners' Association.

Automatic Fog Gun

By E. O. Carter

AN automatic *fog gun* is now being put to active service on the Clyde. The invention consists of a method of obtaining powerful explosions of a mixture of acetylene and air at regular predetermined intervals. The machine is at present made in two sizes, the cost of working being, respectively, about 4 cents and 6 cents per hour.

The writer when in Glasgow recently had the pleasure of hearing the smaller machine at work, and the noise of the explosions was sufficient to take away any desire to hear the larger machine! A powerful acetylene fog gun has already been erected on a rock station off the west coast of Scotland, where it has proved itself much superior to the sonite signals usually placed in such situations, as it is not liable to be exploded prematurely and is not open to the danger of being fired by lightning. Furthermore, it does not require the constant supervision of a keeper to put on charges and fire them, as it is entirely automatic. Once started it will continue until stopped. Where the apparatus is fixed on an isolated rock, and in other situations where a wire connection is inadvisable, it is intended to arrange that it shall be started and stopped from shore by means of a small wireless installation.

The invention is thus admirably adapted for use on buoys and where expense and want of space on which to build prohibit the use of compressed air fog signals.

The present machine is the outcome of years of experiment covering a variety of gases, the mixture of acetylene and air having been found to give the best results.

The Death of James B. Hammond.—James Bartlett Hammond, inventor of the typewriter that bears his name, died at St. Augustine, Fla., on January 27th. He had a varied career. Originally intended for the ministry, he graduated from the University of Vermont, and eventually entered the Union Theological Seminary. He soon gave up the idea of joining the church, and went to Germany, where he studied philosophy. He was a war correspondent during the Civil War. As a shorthand reporter in a Boston court, he first conceived the idea of his typewriter. To this he devoted the rest of his active career. He made a large fortune out of his invention.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Of Interest to Farmers.

DEVICE FOR HOLDING TEETH IN AGRICULTURAL IMPLEMENTS.—M L. AKERS, Pendleton Ore The invention is particularly adapted for holding the teeth of drag harrows against their supporting bars. It provides means for adjusting the teeth quickly perpendicularly to the frame bar of the harrow or at an angle laterally to the line of draft.

DEVICE FOR EXTERMINATING VERMIN ON HOGS.—A W APPLEGATE, Brawley Cal In order to exterminate vermin on hogs Mr Applegate provides an apparatus which may be set up within an opening in a fence or other inclosure through which the animals pass and thereby actuate an oiling device. Means are provided for preventing waste of the oil, and applying to the backs of the animals only so much as is necessary to exterminate the vermin.

STUMP PULLER.—J M PHILBROOK Beach, Wash. The invention is directed to an improved construction of stump-puller adapted to be operated by a draft animal the construction and arrangement being such that the drum on which the rope is wound to pull up the stump is adjustably connected to the sweep arm, so that these arms and the drum are in turning relations with each other only when the sweeps are moving

DRINKING FOUNTAIN FOR POULTRY.—G W GIBBONS, Hadley Ill. The principal objects of this invention are to provide means for preventing chicks or other poultry from fouling or otherwise disturbing the drinking water, to prevent the budding or crowding of poultry about the fountain and to provide a simple compact structure that may readily be transported.

Of General Interest.

COUNTER.—J G BIGGAR, Lincolnmville, S. I., N Y Mr Biggar's counter has a plurality of sections, each having ten parallel ruled lines with holes, in the neighborhood of which are printed the digits and a naught, the sections reading from the right to the left, units, tens, hundreds, etc, so that when a pen is inserted in the 5 hole in the units section, in the 6 hole in the tens section, in the 4 hole in the hundreds section and in the 8 in the thousands section, the sum indicated will read 8,465.

CARD HOLDER.—J A MANSON, 347 W 87th St. New York, N Y The invention relates to a holder for sales cards, which may be readily mounted and which will positively retain the cards in removable position. It consists of a light metal sheet the outer edges of which are turned inward on both sides of the sheet to hold cards upon opposite sides of the same the sheets being mounted upon a suitable support.

PROCESS FOR REMOVING COPPER FROM OTHER METALS.—R R MORENO, care of Bethlehem Steel Works, Allentown Pa Before they are accepted guns must be subjected to proof firing tests with charges of progressively increasing size In these tests copper bands of the projectiles are scraped by the compression slopes and rifle parts until they become fouled with a coating of copper This invention provides for dissolving the copper by an ammoniacal solution in the presence of air

Machines and Mechanical Devices.

SEPARATOR.—C FREDRICKSON, Lock Box 113, Rice Lake Wis. The object of this machine is to separate potatoes into various sizes or grades and at the same time to clean them Means are provided for transporting the potatoes without injury to a separating screen, and dumping or forcing them on the screen while the screen is in operation so that the potatoes will move in a continuous stream

WASHING MACHINE.—J W PIPPIN, Brownwood, Tex. This machine consists of a boiler with a receptacle for clothes therein the receptacle having a perforated bottom and sidewalls. The boiler is placed in a furnace which heats the water in the boiler, converting it into steam and forcing it into the receptacle through the clothes. A disk valve prevents the steam and water from entering through the perforated bottom When the steam is cooled and condensed by passing through the clothes the disk valve drops open permitting the water to return to the lower portion of the boiler

POWDERED COCOA FLUFFER, MIXER, AND COOLER.—P G HOLLSTEIN, care of J M Lehman Co., 13 Laight St., New York, N Y The machine consists of a number of superimposed pans in each of which are revolving arms, acting in succession on the cocoa to cool, stir up, fluff mix and knead the cocoa particles after which they are forced through openings in the bottom of one pan to the next, where the same operation is repeated, and so on through the pan series.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Architecture on Panama Canal

(Concluded from page 101.)

that it strikes us as an architectural hybrid. The slender supporting pillars, carrying a square, shallow platform, from the center of which rises abruptly the massive bulk of the tower, present a combination which, from an architectural point of view, is, to say the least, extremely inharmonious and unbalanced.

This range tower would be an eyesore at any point along the Canal, but standing, as it does, in a particularly prominent position, where it will immediately catch the eye of everyone who makes the transit of the locks, whether they approach them from the Atlantic or from Gatun Lake it will serve to belittle the monumental Gatun locks.

The SCIENTIFIC AMERICAN has always urged the necessity for the collaboration of the architect and the engineer in all cases where there is an opportunity to give architectural expression to engineering construction, and we have never seen a case where the call for such collaboration was so strong as here. The Editor of this journal is no architect, but he has ventured to present the accompanying sketch as showing that the engineering requirements of this problem might have been met in a manner more pleasing to the eye and more consistent with the dignity of the Panama Canal structures.

The cost of reconstructing this particular tower, or at least the lower half of it, would be relatively trivial. We commend the question to the attention of the Isthmian Canal Commission.

Voice-operated Typewriter.

(Concluded from page 106.)

speech will be faithfully recorded in type. However, there are serious limitations which must be considered. In referring to the work of the human typist, we took an example in which no complicated exercise of mental faculties was required, merely a simple word phonetically spelt. Surely in the making up of sentences, starting a sentence with a capital, punctuating it properly, and spelling the words according to the dictionary, a great deal of reasoning power is necessary. What can the machine do in such a case?

The inventor proposes a special form of electric typewriter in which unlimited speed can be obtained by arranging the type bars in a full circle and placing the paper on a vertical cylinder, revolving at constant speed. Then on account of stops between words, a space equal to the width of one or more letters would be automatically produced between the words. Instead of using capitals and small letters, it would be preferable to use nothing but capitals. However, if it were essential to have both capital and small letters, then at the beginning of a sentence a certain little-used sound might be uttered which would operate the shift key of the typewriter so as to produce a capital. The same means could be adopted for operating the period and comma keys. But the principal drawback of the system is that the writing would be phonetic. How can the machine distinguish between "to" and "too" and "two"? Obviously it cannot compete with the human typist, particularly in the English language, as long as we stick to our abominably complicated spelling, unless the dictator comes to the rescue, by pronouncing the words as they are spelled. This would be quite a task with some words, such as "phthisic" or even so simple a word as "laugh."

However, the inventor makes no undue claims for his machine. It is his idea that it might be used as a dictation machine in place of a phonograph. In this connection it offers many advantages, principally because the dictator is able to see just what he has written, and can make corrections and refer back to statements he has already made without laboriously hunting over a cylinder, as is now necessary with the common dictation machine. The phonetic unpunctuated draft made in this way could then be transcribed by a typist. It is quite possible that if the machine were [illegible]

commercial service, it would do much toward the cause of simplified spelling. The man who is accustomed to seeing his letters and other writings typed phonetically would soon learn the advantages of this form of spelling and would be liable to adopt it.

Another possibility of the machine is that it could be connected to a telephone to take down telephone messages automatically and print them on the electrical typewriter. It has also been suggested that the machine could be used to advantage in schools for deaf mutes as it would afford the pupils a means of determining visually the character of the sounds they are uttering in learning to speak.

However, the inventor is not over sanguine of the commercial development of his invention. The apparatus must necessarily be very sensitive. The resonant tones of certain letters are so close that a very careful tuning is necessary and the dictator must learn to talk in a monotone after the machine has been tuned to the fundamental pitch of his voice. Mr. Flowers does not present his invention as a complete solution of the problem of the voice operated typewriter, but merely as a step toward that end which may lead to further development on his own part or on that of other inventors.

Enlargement of the Aswan Dam

(Concluded from page 1.)

from their present position to be set in the succeeding step or where cut down to meet the new situation, while new gates were required for the original No. 1 lock owing to the height of the water being increased.

The thickness of the masonry dam as now completed is increased at the top from 23 to 36 feet and it carries a roadway 29½ feet instead of 18.4 feet wide. The roadway is provided with a track along which moves an eight-wheeled 100-ton crane of 25 tons capacity.

Doubtless the raising of the flood level behind the barrage will be regarded with misgivings by those interested in Egyptian archæology. It was respect for this agitation which induced the government to reduce the height of the first drawings for the dam. Still it must not be forgotten that the very existence of the Soudan depends upon the supply of water for the crops, and accordingly antiquarian must give way to a certain degree to utilitarian interests. The Egyptian government during the past five years, while the alterations to the barrage were in progress, devoted $500,000 to the preservation of all archæological relics within the flooded area. This work was intrusted to Mr. Weigall, inspector for Upper Egypt of the Department of Antiquities, and he has carried out his work in a thorough manner. While a certain number of the ancient buildings now are lost forever and others are periodically submerged, all the most important ruins are secured. Their foundations, which were decrepit, have been strengthened, and a certain amount of judicious restoration has been made in the case of the more dilapidated buildings. All the inscriptions below the high water mark of the impounded water have been carefully copied for preservation, although some of the colored frescoes must unavoidably be damaged by the periodical submergence. True, some of the buildings will be less accessible now than formerly, but the student of Egyptian antiquities need only to select a suitable season for his visit, when he will be able to wander among the ruins with even greater facility than formerly.

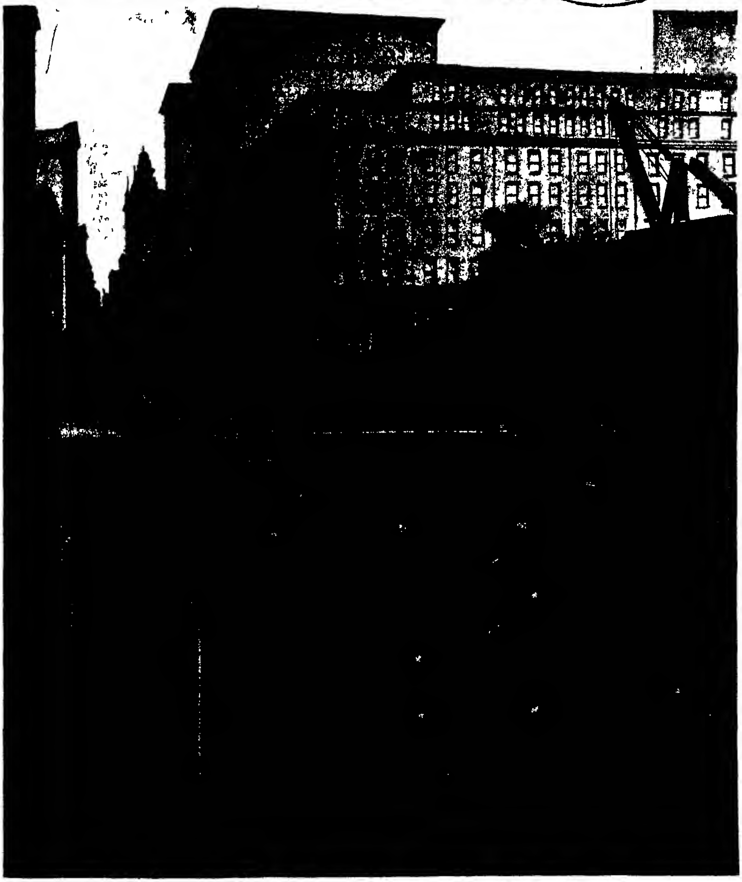
The raising of the dam and the water level virtually completes the irrigation scheme which was elaborated by the engineers and advisers to Lord Cromer's government, although a comprehensive improvement and development scheme in the Delta is in progress. Although the project was severely criticised at the time of its inauguration, subsequent events have proved that the irrigation projects represent the greatest benefits that have been bestowed upon Egypt since its occupation by the British, while financially the scheme is proving a complete success.

SIXTY-NINTH YEAR

SCIENTIFIC AMERICAN

THE WEEKLY JOURNAL OF PRACTICAL INFORMATION

VOLUME CVIII.] NUMBER 7 NEW YORK, FEBRUARY 15, 1913 [PRICE 10 CENTS $3.00 A YEAR



This sectional view, taken at the new City Hall station, shows the construction of the subways by the cut and-cover method by which the material is excavated without any disturbance of the surface of the streets and sidewalks.

A Foolish Measure

IT is simply amazing to learn that a bill has been introduced into the House of Representatives seeking for Government aid in the preliminary work of building a dam or jetty, from 250 to 500 feet in depth and 200 miles long, reaching out into the broad Atlantic from the coast of Newfoundland Of all the foolish bills that have found their way into the halls of Congress, surely this is the most conspicuous. It is the evident purpose of the promotor of this most modest proposal to divert the Gulf Stream, and thereby bring about sweeping climatic changes in the United States in Greenland and over various widely scattered areas of the habitable and uninhabitable globe

We have been asked to comment on this bill, and we do so

The SCIENTIFIC AMERICAN expresses the hope that in the consideration of the scheme, the gift of imagination will be so mercifully tempered by the saving grace of humor, that the measure will be given an early burial, with such obsequies as, in the opinion of the House are becoming to its dignity and importance

New York Pier Problem Settled

IN a characteristically clear and forceful decision, Secretary of War Stimson has effected a compromise between the interests of the Port of New York and the interests of the nation at large which must be considered as a very satisfactory solution of a pressing problem The city of New York had asked permission of the War Department to locate its new pierhead line so that it would run in a direct line from Thirtieth Street to Pier No. 1 at the Battery This would have involved a considerable lengthening of the new Chelsea piers which are located at the narrowest part of the river The War Department took the position and indeed has held it for several years, that no further encroachment upon the fairway at its narrowest point could be allowed Under Secretary Stimson's decision the pierhead line at Chelsea is to remain where it is but the city is permitted to straighten its pierhead line between Gansevoort Street and Pier No 1 This will make it possible to build a dozen or fifteen piers of a length of one thousand feet – sufficient to provide for the growth of ocean steamships for many years to come. Also the Secretary has given permission to straighten out the pierhead line on the New Jersey side of the river between the Morris Canal Basin and the foot of Fifth Street Hoboken a section lying south of the Chelsea reach. This will give similar and even more generous accommodation for the future growth of steamships of the German companies.

As to the more remote future the Secretary refers to the plan of the Board of Estimate and Apportionment which contemplates the construction of long piers between Forty fourth and Fifty sixth streets within the existing pierhead lines. This plan is designed to secure the desired length by excavating back into Manhattan The construction of such piers will be costly and in view of the constantly increasing value of land we would suggest that it would be good policy for the city to purchase at once all the land lying between these streets and extending back as far as Eleventh Avenue This would provide sufficient depth from the pierhead line for piers of a length up to 1,500 feet and it would also accommodate the marginal terminal railway contemplated by the present Dock Commissioner

The Problem of the Mississippi River

THE great flood of the Mississippi River of last year—the largest in recorded history—when the levees were over topped or carried away bodily, and vast areas of the valley were inundated, has created a doubt in the minds of the public as to whether the method of control by revetment and construction of levees was not a failure. This doubt has been freely expressed in the many letters which have been published during the past year in the columns of the SCIENTIFIC AMERICAN We have made no comment upon these letters, many of which suggested alternative and supposedly better plans for the control of the river, and our silence has been due to the fact that we were making a study of the problem from every possible source of information with a view to determining for ourselves whether the present plans for the control of the river or some other were the best to apply in grappling with and controlling this stupendous problem

We have come to the conclusion that the present plan of the army engineers of protecting the banks of the river by revetment and raising the banks by artificial levees to a sufficient height to prevent overflow is not only the best way to control the river, but the only way

If it be asked whether the disastrous inundation of last year does not spell failure, we answer emphatically No The inundation occurred, not because the plan was faulty but because it was incomplete. It was also due to the fact that the existing levees were built only to a sufficient elevation to control the highest flood on record, which the flood of last year greatly exceeded —the maximum flow reaching the enormous total of 2,300,000 feet per second, or twelve times the amount of water that passes over Niagara Falls.

The trouble with the Mississippi work is not that the plans are wrong but that they have been carried out piecemeal and in a somewhat happy go-lucky manner The nation should apply to this great work the lesson which it has learned at Panama A new grade line for the summit of the levees should be established, said line being well above the height reached by the flood of last year, a liberal estimate should be made of the total cost of building these levees, and of protecting the adjacent banks of the river throughout the whole length of the levees with revetments an estimate should be made of the largest annual appropriation of money that could be efficiently expended by the largest force that could be concentrated upon the work, and finally the execution of the work should be placed entirely in the hands of the army engineers with a Col Goethals in supreme and unhampered control

Such an estimate of the total cost of a completely leveed and revetted Mississippi River has been made by the army engineers under the Mississippi River Commission. The total expenditure would be about seventy million dollars for the levee work and about ninety million dollars for the revetment.

Is complete control of the Mississippi River and the absolute prevention of disastrous floods worth the expenditure of one hundred and sixty million dollars? The SCIENTIFIC AMERICAN is decidedly of the opinion that the money would be well spent In the first place, the completion of this work would afford protection to 29,000 square miles of land. The increased value of the land, due to protection is shown by a statement of Col Townsend president of the Mississippi River Commission who has recently testified before the Committee on Rivers and Harbors in the House of Representatives that twenty years ago when he was first stationed in the St Francis Basin land in that vicinity could be bought for a dollar or two an acre, whereas to-day it is worth anywhere from twenty to fifty dollars and even one hundred dollars an acre. Furthermore, there is the humanitarian consideration that this work would prevent the great loss of life and destruction of property which occurs when the river breaks loose. And finally there is the consideration that the completion of this task will constitute a great national work of engineering comparable, in its magnitude and beneficent results, with the execution of the Panama Canal

We will now proceed to discuss the criticisms of the present plan, and the suggestions of alternative schemes of control, which have been made in the many letters referred to above. It has been stated that the whole principle of levee building is wrong, and this for the reason that the matter brought down in suspension is deposited along the bed of the river, which is continually being raised, that this necessitates a raising of the levees which must go on indefinitely As a matter of fact, what takes place is this when the floods come down, the deep pools are scoured out and the material is deposited on the shoals farther down the river, causing a temporary raising of the bottom at these points. As the river falls, the action is reversed, the bars are scoured out and the sand is deposited in the next pool. Careful surveys for several decades show that not only has there been no raising of the river bed, but the cross-section of the river has slightly increased.

As to the proposal to control the Mississippi by building vast reservoirs near the head waters of the river and its tributaries, it may be said at once that the magnitude and cost of such reservoirs and the enormous areas of land that would have to be condemned, render such a scheme impracticable. Its advocates have failed to realize the stupendous magnitude of a problem which involves the control of flood waters that sweep down the Mississippi River at the rate of 2,300,000,000 cubic feet *per second* Testifying on the point, Col. Townsend said before the House Committee "If you were to destroy the whole State of Minnesota, that is, stop every bit of water flowing over it, it would not have made a difference of three tenths of a foot in the height of the last flood at Cairo" Again, if, as has been suggested, the St Francis Basin were converted into a storage reservoir, and the floods were thereby reduced three or four feet in height, it would be necessary to sacrifice no less than seven thousand square miles of country, or the area of a good sized State

Another favorite scheme contemplates the diversion of the Mississippi or of a large portion of its flood waters, by means of sub-channels, or "canals," excavated on one side or the other of the river This suggestion also fails to appreciate the magnitude of the problem If such channels were to be cut, they would have to be leveed in exactly the same way as the river which they were intended to relieve To produce any serious diminution in the height of a river that was passing down 2,300 000,000 cubic feet of water per second, it would be necessary to divert from 400,000 to 600,000 feet per second, which means that an artificial river would have to be excavated and leveed whose flow would be from two to three times as great as the whole flow of the Niagara River

The proposition to straighten out the river by cutting through the bends is impracticable for the reason that while the more rapid flow would relieve the flood, in the districts thus affected, this relief would be obtained at the expense of the districts lower down the river The swifter current of the flood water due to the shorter course, would necessitate a corresponding increase in the height of the levees in the lower sections of the valley

As to the important question of financing the work the simplest and most effective plan of course, would be to do with regard to the Mississippi as we have done at Panama make it a national problem and provide the whole cost from the national treasury. Hitherto the Government has put up so much money, so much has been contributed by the local levee boards, and in one case, at least, the State has made appropriations. It is not surprising to learn that Col Townsend designates such conditions as amounting to practically "an absence of system." Says he "We have just simply been waiting each one doing the best he could—the levee boards have been doing their work and the district engineers have been doing whatever they could with their funds, and it has been a happy-go-lucky method of business."

We believe that the most satisfactory way of financing the project would be for Congress to treat the improvement of America's greatest river as a national undertaking make the necessary appropriations abolish the system of individual boards and place the execution of the work under the one-man control of the army Next to this the best plan would be one of joint Federal and State appropriations, in proportions to be determined by the local advantages secured with the physical design and execution of the work intrusted to the Corps of Engineers of the Army, working under the absolute control of a army officer of proved executive ability

In another year the Panama Canal will be completed Why not move Col. Goethals with his admirable staff and perfectly working system from the Isthmus of Panama to the Mississippi Valley?

Meteorology in the Far East

AT the suggestion of Prof. Nakamura, in charge of the meteorological service of Japan, there will soon be held a meeting of the directors of meteorological observatories in the Far East—the first assembly of its kind. Practical meteorology has made great progress in that part of the world in recent years. Notable steps have been the extension of the Philippine Weather Bureau to outlying islands favorably situated for keeping track of typhoons, the organization of a complete meteorological service in Indo-China, the establishment of a telegraphic weather service along the whole China coast, and to a rapidly growing extent in the interior of China, under the Zikawei Observatory, at Shanghai, the creation by the Germans of a local service for Kiao-chau, with headquarters at Tsingtao, and the organization of an excellent service in Korea, under Japanese auspices. It is understood that China intends to establish a national weather service, with headquarters at Peking, but no details of this plan are yet known.

Engineering

Battleship Costs and the Eight-hour Law.—The Chief of the Bureau of Construction and Repair, Rear-Admiral R. A. Watt, states in his report that the average price per ton of normal displacement of the "Texas" "Nevada," and "Oklahoma," which are being built under contract under the eight-hour law, is $215.26. The average price of the three preceding battleships, built by contract when the hours of labor were unrestricted, was $177.05 per ton of normal displacement, and for the five preceding vessels it was $180.99 per ton.

Prosperity in British Shipbuilding.—Just now the British shipbuilding yards are experiencing an extraordinary run of prosperity. The total tonnage of all ships under construction for merchant and navy service reaches the huge total of 2,466,940 tons, of which about 500,000 tons consists of warships for the British and other navies. In 1909, a period of depression 764,520 tons of merchant ships was built, or rather was under construction. To-day there is under construction 1,970,065 tons of merchant ships.

To Dock the Largest Liners.—The city of Boston is to be congratulated on its enterprise in appropriating $3,000,000 for the construction of a drydock capable of taking the largest ocean liners. The construction of such a dock at New York has been the subject of much talk but little action. A 1,000 foot dock is liable to be at any time most urgently needed. Had the "Titanic" been able to crawl into New York harbor, she might have had to stay here indefinitely, for there is not a dock in the country that could accommodate her.

Surprise Signals for Locomotive Engineers.—In view of the many accidents on the New York, New Haven & Hartford Railroad, due to engineers running by signals, the company has ordered a series of test surprise signals. According to a dispatch from New Haven, the tests will include improper train orders, displaced switches and a number of changes of signals. Tests of this character act as a strong inducement to strict watchfulness and obedience on the part of trainmen generally. The practice is followed on several roads, we understand, with excellent results.

Perkin Medal for James Gayley.—The Perkin Gold Medal was recently awarded to James Gayley, formerly first vice-president of the United States Steel Corporation. Gayley is the seventh recipient of the medal, which was created in honor of Sir William Henry Perkin, the founder of coal tar chemistry, which revolutionized the dye and drug industry. The medal was awarded to Mr. Gayley for his invention of the dry-air blast for the manufacture of iron. This invention brought about a reduction of at least $1 a ton in the cost of producing pig iron, besides making it possible for the iron master to produce in all weathers a product of uniform quality.

The Selection of Locomotives.—In the paper before the American Society of Mechanical Engineers in this city, Mr. O. F. Bever, Jr., speaking on the question of the selection of locomotives in relation to the economics of railway operation stated that the main steps in this selection may be divided into: The consideration of the service, the nature of the business, the topography of the road, train speed, and train resistance, types and sizes of locomotives available, improvements to the permanent plant, effects of various types and sizes of locomotives on operating expenses, and the final selection of the most economical type and size of locomotive.

Length of Piers at New York.—On May 14th the world's largest steamship the "Imperator," is due at this port. She is 910 feet long. The longest permanent piers on the Manhattan side of the Hudson River are 825 feet long and these are leased by the Cunard Company. The White Star Company dock the "Olympic" at an 800-foot pier, which has been temporarily lengthened to 900 feet, but the extension must ultimately be removed. On the Jersey side the North German Lloyd has a 900-foot pier. The Hamburg-American Line, owners of the "Imperator," have an 850-foot pier. To dock the big ship this pier will be lengthened to 950 feet. Secretary Stimson's recent decision provides for 1,000-foot piers.

Cuniberti on Battleship Protection.—At a recent meeting of the Corps of Italian Naval Architects, Major-General Cuniberti doubted whether the means of defense of modern battleships of the dreadnought type had progressed proportionally to the increase in their offensive power. He considers that a naval battle at ten thousand yards would demonstrate that gun-power was "vastly superior to the resistance of the armor protecting the ship attacked." He would concentrate the protection, but he realizes the difficulty of determining exactly which sections of the ship should be more adequately defended. Very interesting to us is his statement that the dreadnoughts of almost all the navies, except perhaps those of the United States, are very deficient in regard to protection. Undoubtedly Cuniberti had in mind those two heavily protected ships, the "Nevada" and "Oklahoma," which we consider to be by far the most efficient all-round fighting units to be found in any navy to-day.

Electricity

Electric Trucks in Boston.—In 1902 the first electrically-driven delivery wagons were introduced in Boston. There were only two cars that year, in 1905 the number had increased to ten, in 1910 there were 119 electric trucks, and in 1912, 279, an increase in the last two years of 134 per cent.

Electrification of a Rocky Mountain Railroad Line.—The Chicago, Milwaukee and Puget Sound Railroad is to electrify 450 miles of its main line between Harlowtown, Montana, and Avery, Idaho. The Great Falls Power Company which will furnish the electric power has received a fifty-year grant from the Department of the Interior to transmit current over public domain under strict government regulations.

Transmitting Range of Arlington Station.—In order to determine the maximum range of transmission of the new wireless telegraph station at Arlington, Va., the cruiser "Salem" has been sent out upon a voyage over the Atlantic. The cruiser will endeavor to keep in touch with the Arlington station and determine the exact distance or distances at which signals sent out from Arlington cease to be perceived. It is believed that the Arlington station will be able to transmit over a radius of 4,000 miles.

Electric Service Table.—A table has recently been put on the market which is of the ordinary library type but is also provided with four or more outlets or plug sockets, inconspicuously placed on the side below the table top. This affords means for connecting up electrical apparatus such as fans, cooking utensils, reading lamps, etc. In an iron box secured to the under side of the top are a meter, main switch fuses and the necessary wiring. Connection with the lighting main may be made through a steel conduit passing from the iron box through the baseboard to the outside wall of the building. This simple device comprises all the electrical outfit necessary for the electrical comforts of a living room. By using extension cords a vacuum cleaner may be efficiently employed all over the house.

Electricity in the Drafting Room.—Two applications of electric heating in connection with drafting work are referred to in an English electrical magazine. One is the use of a portable combination heater and fan ordinarily employed by hairdressers to dry their customers' hair after washing, to dry the ink on tracings. This "wrinkle" shortens the time required to complete the tracing as the freshly inked lines must be dry before T-square or triangle can be moved over the tracing, and in the damp climate of the British Isles the scheme might find considerable application. The other idea, which has been used in this country also, is to dry blueprints by going over them with an electric flat-iron, and the flat-iron is also useful to straighten out tracings and prints that have been rolled or folded.

Mercury-vapor Rectifier of Large Power.—In the ordinary mercury-vapor rectifier using a glass vapor chamber the amount of electrical energy that can be converted from alternating to direct current has been limited, and the use of this form of energy converter has been confined to such comparatively small power applications as the charging of automobile storage batteries from alternating current mains and similar light work. A recent German type of rectifier has been developed for converting larger amounts of energy, the inclosing vessel being a sheet-steel cylinder. The gas-tight joint is formed by a double packing of asbestos or similar material with a layer of mercury in between. A 220-volt, 80-kilowatt rectifier of this type has been in use since November, 1911, supplying the power plant of an iron foundry for 10 hours daily, operating from single-phase 2,000-volt mains. A 100-kilowatt steel rectifier weighs only 1,000 pounds as compared with the 4,200 pounds weight of an ordinary rotary convertor of the same capacity.

Exploring for Gas with Electric Arcs.—During the excavation of the tunnel through the Santa Ynez Range in California for the Santa Barbara aqueduct, so much gas was encountered that special means had to be devised for the protection of the workmen. It was decided to ignite the gas with electric arcs. For this reason arcs were placed in pockets in the roof of the tunnel, about 200 feet apart. Half an hour after a blast was fired, the arc circuits were closed, and by means of ammeters it was possible to determine whether they were burning. If no explosion of gas resulted from this, the fire boss entered the tunnel and proceeded a distance of 3,500 feet to the second arcing station. Here the current was again switched on, and if there was no explosion, he proceeded with his gang of men to explore the tunnel with a safety lamp in search for pockets. This done, torches were placed throughout the tunnel at distances of about 100 feet apart through the section in which the gas was encountered, and were kept burning while the next shift was at work on the heading. Four hours were thus consumed in precautionary measures, between shifts.

Science

Solar Radiation Concentrated by Clouds.—In the Bulletin of the Mount Weather Observatory Messrs. H. H. Kimball and E. R. Miller call attention to the paradoxical fact that clouds, when favorably situated sometimes increase the intensity of radiation from sun and sky received by a body on the earth as much as 40 per cent over what would be received if the sky were perfectly clear, while increases of 10 per cent from this cause are quite common. This is shown by the records of the horizontally exposed Callendar pyrheliometer, which makes a continuous registration of the vertical component of the radiation from sun and sky, and the phenomenon is explained by the fact that radiation reflected from the cloud surface is added to that coming directly from the sun.

The International Map of the World on a scale of 1 to 1,000,000 will when completed eight or ten years hence cover a total area of about 1,840 feet by 75 feet, or the surface of a globe 40 feet in diameter. It will consist of about 1,500 sheets each representing a section of 4 degrees in latitude and 6 in longitude. The first sheet of the United States portion has just been published by the Geological Survey in Washington. It is known in the general scheme as "sheet North K 19," but will be more popularly known as the "Boston sheet," and embraces Rhode Island, and portions of New York, Connecticut, Massachusetts, New Hampshire, Maine and Nova Scotia. It is printed in six colors. Ocean depths and terrestrial altitude are shown by contour lines and graduated tints. It represents the beginning of a more accurate map of the United States than any that now exists.

Ozone for Preserving Meat.—An important improvement in the technique of cold storage has recently been introduced in Germany, viz. the use of ozone as a supplement to the ordinary process of refrigeration. In the cold storage rooms attached to slaughter-houses the temperature of the air is liable to be raised to a serious extent when the doors are left open for any reason, for instance when meat is being put in or taken out. The microorganisms of putrefaction immediately become active under such circumstances and the keeping quality of the meat is diminished. Now it is well known that ozone is a powerful germicide. If the air of the cold storage room is ozonized, its temperature may be raised without injury to the contents. This has been proved by numerous experiments, and ozonizing apparatus has now been installed in the abattoirs at Cologne, Potsdam, Brandenburg, Berlin, Frankfort-on-the-Main, Düsseldorf, Freiburg (Silesia), Aix-la-Chapelle and Erfurt, in a cold storage depot in Hamburg, and in various dairies, poultry and game stores and fish establishments.

The Progress of Aerology.—*Petermanns Mitteilungen* publishes an abstract of the presidential address of Prof. Dr. Hergesell at the seventh meeting of the International Commission for Scientific Aeronautics, held in Vienna, May 27th to June 1st, 1912. (This commission, by the way, has a misleading name, as it is not concerned with the navigation of the air, scientific or otherwise, but with meteorological investigations carried on with the aid of kites and balloons.) The president reported that since the commission last met, in 1909, twenty aerological stations had been added to the international *reseau*, including some in countries where no upper-air research had previously been carried on, viz. the Dutch East Indies, Argentina, Uruguay, Iceland and Canada. The commission has two observatories under its immediate direction, one on the peak of Teneriffe, and one in Spitzbergen. The former has made observations of the trade and antitrade winds up to an altitude of 11 miles by means of more than 800 ascents of pilot-balloons. The latter is making important researches on the atmospheric circulation around the North Pole, especially in co-operation with various Arctic expeditions.

Micrometer Positions of Halley's Comet.—In the *Astronomical Journal* (No. 10, Vol. XXVII) Prof. F. E. Barnard publishes some micrometer positions of Halley's comet made with the 40-inch telescope of the Yerkes Observatory. Prof. Barnard states that in the last few observations before its final disappearance it was excessively difficult to make the measures, partly because of the poor condition of the sky. Still Prof. Barnard is so accurate and skillful an observer that his data will undoubtedly be accepted by every astronomer. The small field of the 40-inch telescope made it difficult to secure proper comparison stars on observations. Hence it was necessary in many cases to connect the comet with a faint star near it and then to compare this with a known star. The positions of these intermediate stars are given in Prof. Barnard's paper. Prof. Barnard also publishes in the *Astronomical Journal* a few notes made at the time of observation, and promises to publish in a later paper the main mass of notes. "These last give a detailed description of the naked eye appearance of the comet, and I think," Prof. Barnard states, "will be of service to astronomers at future returns of this object. Such information seemed to be sadly lacking in 1910 in connection with the return of 1835."

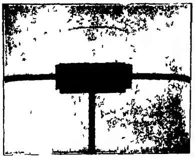

Fig 1.—Side view, showing cylindrical shape of wave

Fig 2.—A simple sound wave seen end-on.

Fig. 3.—Sound wave reflected from plane surface

Fig. 4.—The same wave, photographed a moment later.

Seeing Sound

Snap Shots of Waves Traveling at Seven Hundred and Fifty Miles Per Hour

IN our day one does not need to be a physicist to know that wave motion of one kind or another plays an important part in nature and in technical applications of natural phenomena. The simplest and most obvious type of wave motion, the one to which the name is primarily applicable, is that which we observe in the ripple in a teacup, a surface-tension effect, or in the mighty ocean billow rolling on under the action of gravitation. Such waves are essentially two-dimensional; at least their direction of propagation lies in a plane. A typical wave front in this case, such as that produced by a stone falling into a pond, is circular in form.

Other waves, and a very important class, are three-dimensional, the typical form being spherical, each wave starting out from a point source and spreading out as a sphere with that point as its center. Light waves are of this character, as well as the waves used in wireless telegraphy. In fact, as our readers know, the two are propagated with the same velocity through vacuum, and are identical in character except as regards their wave length, which is of the order of one fifty thousandth of an inch in the case of light, and of the order of several thousands of feet in the case of the electric waves commonly used in wireless telegraphy.

While the circular waves on a sheet of water are readily observable and known to every child, it is only by special means that spherical waves can be rendered visible. Light waves are themselves of course invisible—contradictory as this may seem. A beam of light passing through a perfectly dustless space is absolutely invisible to an eye looking across the beam. In this sense it may indeed be said that no eye has ever seen a wave of light. But there is another kind of spherical waves—sound waves—which, though ordinarily quite as invisible as waves of light or electromagnetic waves, can nevertheless, by suitable means, be rendered observable to the sense of sight. A particularly fine method for effecting this has recently been developed by Prof. A. L. Foley of Indiana University, in collaboration with Mr. W. H. Souder. By the kind permission of Prof. Foley and the courtesy of the editor of the *Physical Review*, in which the first account of this method appeared, we are enabled to give here an indication of the nature of the process followed, and to show some of the very fine photographs obtained.

The method is best explained by reference to the diagram Fig. 5, which shows the apparatus employed.

Four spark gaps S, I, T_1K_1 and T_2K_2 are arranged in series in a circuit in which a large electric induction machine is included.

The gaps T_1K_1, T_2K_2 serve merely as a means for producing a spark at the desired moment by turning the glass plates GG out of the way—these plates being normally interposed between the knobs T_1K_1, T_2K_2.

Every time a spark is thus caused at T_1K_1, T_2K_2, a similar discharge occurs at the gaps S and I also. The sound gap S is so arranged as to give a loud discharge, thus sending out a sound wave consisting of alternate layers of compressed and rarified air. The gap I, on the other hand, has its terminals made of magnesium wire, so as to give a brilliantly luminous discharge. The Leyden jars K_1, together with other features that cannot be discussed in detail here, serve to delay the discharge at I so that it occurs by a minute fraction of a second later than that at S. Hence the light from I arrives at S when the sound wave has traveled a certain distance out from its source. A photographic plate (or the observer's eye) is placed at P, and as the layers of air of different density of which the sound wave is formed, have different refracting powers, the appearance shown at P is that of a dark ring on a light background.

The waves produced by this apparatus are not strictly spherical in form, but consist of cylinders with hemispherical ends. As these are viewed end on, however, the appearance presented is exactly the same as if we were dealing with spherical waves.

Of the photographs so obtained we reproduce a few typical examples. Fig. 1 is a broadside view showing the cylindrical form of the wave. A simple transverse

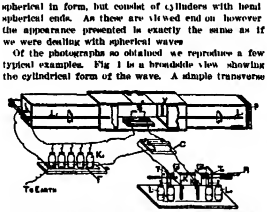

Fig. 5.—General view of apparatus employed in photographing sound waves.

section is shown in Fig. 2. Very interesting is Fig. 3, which shows the appearance presented when the wave hits a reflecting plane obstacle ("mirror"). The forward part of the wave (on the right) travels on unchanged, but a similar secondary (reflected) wave is produced at the reflecting surface and travels out in pursuit of the original wave as seen in Fig. 4, which represents the state of affairs at a slightly later instant.

The action of a lens (sulphur dioxide contained in a collodion envelope) is shown in Fig. 6. It will be seen that the wave starting from the focus of the lens on the right, emerges as a plane wave (parallel rays) on the left. A similar effect produced by a parabolic mirror is shown in Fig. 7. Here also the wave emerges after reflection as a plane wave. A very interesting case is shown in Fig. 8. A wave starting out from one focus of an ellipse (at which the knob of the sound gap appears) is reflected and brought to a point at the other focus of the ellipse. Finally, a very fine interference pattern is produced, as shown in Fig. 9, by a cylindrical grating placed in the path of the sound wave with the source at the center.

It may be remarked that more recently Prof. Foley has further extended his researches, using the method here outlined, for the study of the electric spark discharge.

Those of our readers who may be interested in the details of the experimental arrangement designed by Prof. Foley will find a full account of these in the current issue of the SCIENTIFIC AMERICAN SUPPLEMENT.

The New Campanile at Venice

THE new campanile of Venice shows some interesting points of construction. When it was decided to rebuild it, the principal question was to provide against a repetition of the catastrophe which befell the original tower. It is known that Venice, constructed as it is upon the lagoons, gives a very defective foundation soil, and this appears to be the reason why the old campanile fell down, owing to the overloading of the foundations. In fact, the tower had 280 feet height and over 13,000 tons weight, and gave a pressure of 1.3 tons per square foot upon its foundations. In erecting the new tower the commission provided for better conditions by strengthening the foundations and at the same time lightening the weight of the construction by another method of building, also by consolidating the different parts of the tower so that there is no danger of dislocation. Reinforced concrete came in very well to carry out these ideas, and it enabled the engineers to give more space to the interior without changing the outside appearance in the least. The side walls are now very well joined together by means of the spiral staircase which passes up through the center of the tower so that the whole mass has a much greater solidity than before. The use of reinforced concrete allowed of reducing the thickness of the walls considerably, and the new construction now has three quarters the weight of the old one. For the foundation over 1,000 new piles were driven so as to make it much stronger than before. The piles uphold a foundation base in hard stone, and the load upon the ground is now reduced to 4.7 tons per square foot, which is well within safe limits. The spire which terminates the tower and is 98 feet in height is well braced inside by reinforced concrete members and rests upon a platform foundation of the same material. Only the framing for the support of the bells is of metallic construction. The elasticity of this part as well as the greater flexibility of the whole edifice, is counted upon to reduce the oscillations of the tower upon the foundations due to the effect of the wind and also the vibrations caused by the bells. It is thought that these effects played a large part in the destruction of the former tower, and that they will now be overcome to a great degree. On the whole, the builders used great pains not only to keep the outside appearance of the tower as nearly like the old one as possible, but to redesign the body of the construction on the most modern principles in order to obtain the greatest possible strength, and thus diminish the likelihood of any similar accidents in the future.

Co-operation in Educational Effort

THE recently issued annual report of President MacLaurin of the Massachusetts Institute of Technology discusses the need of co-operation in educational effort. To the students and alumni of the Massachusetts Institute of Technology the question is one of great importance in view of the proposed merger of the Institute with Harvard University. Admitting that there has been much friendly co-operation between Harvard and Technology, and prophesying an even closer relation in the future, now that the Institute is about to move to Cambridge, President MacLaurin nevertheless maintains that with regard to any scheme that might be proposed to meet the actual conditions at Harvard and Technology, it is impossible to maintain extended co-operation with any satisfaction to either institution, and consequently with any chance of permanence unless the idea of competition is eliminated. Furthermore, he maintains that extensive co-operation to be worth much consideration must be broad enough to throw open the resources of both institutions (in equipment as well as in men) to at least some of the students of the other. He also insists that the obvious way to co-operate is in the treatment of the graduate students, leaving the greater part of the Massachusetts Institute of Technology entirely alone.

The necessity for co-operation in educational effort is nowhere more apparent than in the relations of technical institutions to our universities. Education suffers in few ways so much as through lack of co-operation among those colleges, universities, and schools of applied science which not only should be laboring together for the common good, not only should be avoiding by agreement those duplications of resources and of effort that keep them all painfully poor but also should be devising some plan by which students may be transferred from one to another without loss of time and effort.

A few examples may give definiteness to these general statements. If Harvard were to duplicate the complete mining and metallurgical laboratory which the Institute of Technology is planning to build and equip, the community would be called upon to expend hundreds of thousands of dollars for mere duplication, and yet all the students of mining and metallurgy at Harvard could easily be accommodated in the Institute's new laboratory without detriment to the Technology students. Similarly it would be folly for the Massachusetts Institute of Technology to spend hundreds of thousands of dollars to duplicate the University's museum, whose great collection of minerals and fossils might be opened to the senior students at Technology without inconveniencing the regular students of Harvard. The building of an experimental tank in the Institute of Technology a step considered by competent authorities to be a necessary part of a department that is fully equipped to advance the science of shipbuilding would suffice very easily for two or more neighboring institutions.

Such duplication, however, does not represent the entire waste of the present system. "More serious than any duplication of machines," says President MacLaurin, "is the loss that falls upon the community by excluding advanced students of each institution from the benefit of coming under the influence of the pioneers of science in the other institution, men whose character and attainments make any suggestion of duplication absurd. For years the advanced students of geology at this Institute have been stimulated by Prof. Daly's skill and enthusiasm as a teacher as well as by his scientific achievements. Now that he has gone to Harvard, it is regrettable that such students should be cut off from his influence, especially in view of the fact that the advanced students of Harvard and Technology together would not be too many for a man of his capacity to deal with effectively. Indeed, in such cases there is a loss rather than a gain in efficiency, merely from the educational standpoint, where the number of students is unduly small."

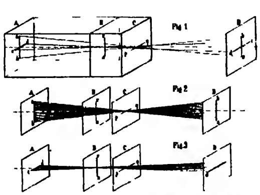
President MacLaurin's discussion of efficiency in education was rendered necessary by the decision that there can be no merger with Harvard. The Institute seems strong enough to stand alone or to enter, if it wishes, into relations of co-operation in educational effort. Because the latter term might be misunderstood, and serve for a cause of dissension, President MacLaurin laid down the broad fundamental principles of co-operation with Harvard.

Anomalies in Automobile Terminology.—Automobile terminology, to many of those who call themselves engineers, must be a despair if their efforts at elucidation and the naming of parts can be taken as a guide. Despite the evident redundancy, apparent in the derivation of the word "pedal," "foot pedal" is one of the most common of errors that appears in nearly every piece of automobile advertising, while one "engineer" who would be more than ordinarily explicit has advertised that the brake is operated by the "right-hand foot pedal."

The Slit Camera

By Our Berlin Correspondent

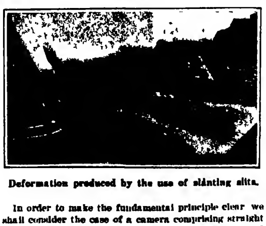
THE slit camera, designed by Mr. Wolfgang Otto, of Kiel, Germany, is an ingenious device on the pinhole camera type, and is intended for producing any distortion desired. It comprises on the side turned toward the object, two crossed slits arranged in partitions situated behind one another. The slits may be straight or curved, of any width desired, and the distance of the partition from the plane of the image may be varied at will. The partitions may also be curved or slanting if desired. The camera can, of course, be designed at will as folding camera, bellows camera, etc.



The Otto slit camera for producing distorted photographs

Block of houses fore-shortened vertically by the slit camera

The same block with vertical lines exaggerated in length



Deformation produced by the use of slanting slits.

In order to make the fundamental principle clear we shall consider the case of a camera comprising straight slits of uniform width, the plane of the image A and the partitions B and C being vertical, while one of the slits ($p\ q$) is horizontal and the other ($r\ s$) vertical. The picture of the object $a\ b\ c\ d$, which is then produced on the screen D shows a deformation, the scales in a horizontal and vertical direction, respectively bearing to one another the same ratio as the distances of the two slits from the focal plane.

If we follow a moving point along the line $a\ b$ of the object at D (Fig. 2), the beam of light passing from such point to the image screen at A will, as it were, pivot about the slit $p\ q$ in the partition C. Similarly if the point of the object considered moves horizontally along $c\ d$, the corresponding beam of light will pivot about the slit $r\ s$ in the partition B and the same applies to the horizontal beam of rays represented in Fig. 3.

Thus vertical lines of the object are thus gathered into an image at A by the slit $r\ s$ while horizontal lines are similarly gathered into an image by the slit $p\ q$. Owing to the difference in the distance of the two slits from object and image they form two images of different magnitude. But this amounts to saying that the resultant image represents vertical and horizontal features of the object on two different scales—or in other words the resultant image is distorted.

Other deformations may be produced by providing slanting partitions, slits of varying width or curved. In many cases the conditions determining a given deformation can be found by calculation. Moreover instead of a single slit any number of slits can be provided in the same plane.

The slit camera is not a mere scientific toy but can serve many useful purposes. Thus it may be used for rapidly altering architect's plans, or for producing comical caricature effects by deformation, for varying any given pattern for fabrics or carpets, and for altering the different forms of type.

The slit camera can be readily made by everybody and will be found an inexhaustible source of amusing experiment.

Popular Ignorance About Our Common Woods

MODERN culture in no small measure despises natural history. Wood experts observe constantly from their intercourse with their fellows that even among the well educated people there prevails a general lack of acquaintance with the commercial woods. Among the wood users of the present day what knowledge they have upon the woods is generally that of a few superficial and unrelated facts mixed, perhaps, with a number of incorrect ideas concerning their physical properties and their suitability for certain uses. It is also a rather remarkable fact how prone people are to confound the names of well known species of woods, which though closely related possess notwithstanding clearly marked distinctive characters. Thus, experienced lumbermen or timber merchants call spruces firs, pines spruces, maples "sycamores," and even trained foresters sometimes class the cigar box cedar (*Cedrela odorata*) with our common red cedar or juniper. This confusion of knowledge exists also with relation to species which have been made familiar to a number of laymen in the local lumber yards where for instance western yellow pine is sold as white pine, and red oak as white oak.

There is no material in such common use as wood, and it may be from this very circumstance of its being so plentiful that it is looked upon by people as beneath their notice. The average man in the street is unable to tell the distinctive features of the wood of ash and that of chestnut, and he does not regard such facts entitled to any consideration. The same person would feel offended if he were told that he did not know the difference between a mushroom and a toadstool, as a matter of fact there is no botanical or other distinction whatever. A knowledge of the chief external appearance of wood and their more prominent structural characteristics will be found upon investigation to be highly interesting and often prove to be of considerable value. It is a knowledge and understanding of the characteristics of our common woods by which the relation of structure and external features is clearly indicated and defined that the people generally are most lacking. Not many possess the ability to group woods having like structural characters.

The study of woods has indeed latterly received more attention than formerly as a branch of education and made a part of the courses given in forestry and other technical institutions. It should be made a part of the common school exercises. But the teachers have themselves no very clear understanding of the characters of the chief commercial woods, and a short course of instruction must first be introduced into our training schools for teachers. Instructions of this character can fitly be introduced in connection with sloyd work.

There is hope that the coming generation will be better posted upon the principal characteristics of woods. In this respect the people of Germany have progressed considerably more than the English or the Americans. The Latin names employed for a good many structures in wood have been perhaps the chief difficulty, and discouraged many persons from acquiring a better knowledge of woods. This difficulty is now fast disappearing, for easier terms are being applied to such structures which are most essential to a knowledge of woods.

Building a Four-track Tunnel Beneath Broadway, New York

DWELLERS in Manhattan, and outside of it for that matter, will long remember the intolerable discomfort which attended the construction of the present subway. Unsightly cableways stretched above chasms which yawned where once the street had been, sidewalks were littered with timber, tools and the various impedimenta of the contractor, carts backed up to receive the excavated material, selecting loading positions which, though they may have suited the convenience of the contractor, certainly had no reference to the comfort of the street and sidewalk traffic. Dust in summer, dirt in winter—obstructions everywhere, the four or five years spent in building the first subway developed a prejudice against the new transit system, which it took all of the road's admitted excellence for the first year or two of its operation to dissipate.

We learned well the lesson taught in 1903 and adjacent years. In 1913 we are again building subways, but we are doing it with many notable differences, the chief of which is that the many nuisances which accompanied the earlier work have been entirely abolished from the new work. Formerly a whole section of the street, or if that particular neighborhood were fortunate, one half of the street, was closed and a huge open excavation was maintained until the work had been carried down to the full depth. That was what the engineer calls excavation by "open cut." To-day our subways are built by what is known as the "cut-and-cover" method, which is being so carefully and conscientiously followed, that a large proportion of the millions of people that pass up and down Broadway on foot, in motor, or on street-car, are in complete ignorance of the fact that a four-track express railroad is being built in a tunnel immediately below.

On the front page of the present issue is a drawing which explains how this work is being done. The view is taken on Broadway at the point where the new City Hall Station of the new Broadway line is being constructed. South of the City Hall the route lies under the streets to the west of Broadway until it reaches the Battery, when it passes below the East River to a junction with the Brooklyn Rapid Transit System. North of City Hall Park the subway extends up Broadway to the neighborhood of Times Square, and thence up Seventh Avenue to Fifty-ninth Street, where it will turn to the east through Fifty-ninth Street and cross the Queensboro Bridge to Long Island City.

The section of the work herewith illustrated, which is being built by the Degnon Contracting Company, to whom we are indebted for courtesies in our examination of the work, extends from Walker Street to Park Place, a distance of about 2,800 feet. The tunnel contains four tracks as it approaches the station, which contains five tracks. Two of these are carried on an upper deck, the other three below, the total depth of the excavation here being about 41 feet, and the total width something over 75 feet. The material is favorable for excavation, being entirely sand, of which there are in this section about 250,000 cubic yards.

A most important work, preliminary to the excavation, was to remove two gas mains, 12 inches and 16 inches respectively in diameter, temporarily from the excavation and carry them above ground—this to guard against possible explosions due to leakage. The mains were diverted at each end of the work, and carried above the sidewalk upon temporary trestles, as shown in the front page engraving.

The first operation in excavating by the "cut-and-cover" method is to sink a series of shafts, placed generally on the side streets, just off Broadway. These shafts on the City Hall section were sunk at the Park and at Worth and White streets, and they were carried down to the depth of the first bench of the excavation, or say about 16 feet. The next step was to remove the street paving for its entire width and for a length along the street of forty or fifty feet, and lay down a series of parallel longitudinal 10-inch by 10-inch timbers, spaced five feet apart. On these was laid a roadway of 5-inch plank. The space between the two tracks was covered by two layers of planking, one of 3-inch and one of 4-inch, the first transverse and the second, or upper layer, longitudinal. When this was done a smooth roadway of timber was thus provided in place of the asphalt or Belgian blocks.

The excavating gang then entered the side shafts, and with pick and shovel began to excavate across the street. As the work advanced, they placed 12 by 12 posts beneath the 10 by 10 timbers which carried the roadway planking, the excavation being carried on until it was completed to the opposite side of the street. Temporary footings for these posts were placed on the bottom of the excavation; the transverse lines or bents of supporting timbers were placed ten feet apart, measured in the direction of the street.

The excavation and timbering, as thus described, was carried down to about the 16-foot level below street grade. Above this level, it will be remembered, the supporting posts were placed at 10-foot intervals; below, the character of the construction made it necessary to place the posts at 20-foot intervals. Moreover, it was desirable to put these posts, which were 25 feet long and reached to the final bottom of the excavation, in place before the dirt was taken out. To do this, timbered shafts measuring 3 feet by 4 feet were sunk down to subgrade, and into these the 25-foot 12 by 12 posts were lowered, a concrete slab having been prepared at the foot of each shaft, as a footing or foundation. At the top of the 25-foot posts were the caps and longitudinal stringers, upon which the upper and shorter lengths of posts rested, and which served to tie the transverse bents together. The whole system of falsework was thoroughly braced, as shown.

The excavation was done by pick and shovel, the dirt being loaded into buckets, on small contractors' cars, which were pulled back from the headings to the hoisting shafts either by mules or electric locomotives, where they were hauled up by electrically operated derricks and dumped into hoppers. The latter were built on platforms spanning the street or the sidewalk, which were capable of holding thirty yards apiece. From the hoppers the material was dropped directly into the contractor's carts, which carried it to the dump or wherever it was being disposed. The disposal of the excavated material is one of the serious problems of city subway construction.

Some very successful excavating was done by means of a belt conveyor and elevator. The conveyor extended across the cut opposite the hoisting plant, which was located in the shaft near the corner of Chambers and Broadway. The material was hauled in cars by electric locomotives, dumped into a hopper, loaded onto the belt conveyor, and carried to the boot of the elevator, whence it was taken up and deposited in hoppers upon the platform.

During the progress of excavation the sidewalls of the tunnel are protected against caving in by means of three lines of vertical sheet piling driven as shown in our front page illustration. The piling is braced by a series of 10 by 10 struts, which are carried back and bed against the longitudinal timbers of the 25-foot carrying posts already referred to.

When the excavation had been carried down to subgrade the heavy floor of concrete about 2 feet 6 inches in thickness was laid, and the work is to-day so far advanced that the concrete floor is completed for a length of 500 feet.

The next step will be the erection of the steel columns, the construction of the steel work of the floor and roof and sidewalls, and the turning in of the concrete arches which, with the embedded steel, will form the sidewalls and roof of the finished structure.

An important and costly section of this subway building is the provision which must be made for supporting the front walls of the buildings which line the route of the tunnel. In the case of the more recent buildings, whose foundations have been carried down to rock, no change is necessary; but in the case of older buildings, such as the Stewart building shown on the right in our illustration, whose foundations were far above the bottom of the tunnel excavation, it was necessary to resort to "underpinning."

Steel needle beams were run at intervals through the foundation walls, their ends resting upon timber posts of sufficient strength to carry the entire load of the front wall. Masonry was then built in below the wall until the latter continued without a break down to a point slightly below the floor of the subway.

It will interest the readers of the SCIENTIFIC AMERICAN to learn that the first tunnel below Broadway, constructed over forty years ago, on the plans of the late Alfred Ely Beach of the SCIENTIFIC AMERICAN, was located at the point where the section shown on our frontispiece was taken.

Our thanks are due to Mr. Burdette Kipp, assistant engineer, and Mr. R. P. Hustin, engineer in charge, for their courteous assistance in furnishing opportunities for the preparation of this article.

A Feathering Air Propeller

IN the mechanical engineering laboratory of Columbia University a test was recently made of a feathering air propeller invented by Ciro F. Mendez. The propeller was eight feet in diameter and weighed 193 pounds. Of this weight 76 pounds was the weight of the blades and 117 pounds the weight of the hub and the mechanism for feathering the blades, a weight not excessive for a dirigible airship propeller.

In carrying out the test the propeller was mounted on a frame free to move in a horizontal direction by the action of the propeller upon the air. The amount of thrust was measured in pounds by a spring balance. Power was applied from an electric motor through belting in such a manner as not to affect the movement of the table; in other words, power was applied directly over the center of rotation; the weight of the frame of the propeller was carried upon anti-friction rollers, and the friction error was eliminated by measuring the pull, including the friction and minus the friction, adding these together and dividing the result by two. A series of runs 155, 200, 250 and 300 revolutions per minute were made and the amount of current and thrust recorded. After the capacity of the apparatus had been learned, a brake pulley was attached to the propeller shaft and arrangement made for reading directly the amount of power transmitted to the propeller. In this series of tests, the propeller was driven at each of the speeds referred to and the readings of the voltmeter and ammeter recorded; also, the thrust of the propeller. Then the coupling in the propeller shaft was disconnected, the brake band and the brake attached, and the test run at the same reading of the voltmeter and ammeter, thus determining the actual power delivered to the propeller and eliminating the electrical and mechanical efficiency of the motor, belting and shafting.

The amount of work done by a propeller is its resistance against revolution, measured by its thrust, multiplied by the distance of travel of the center effort of the blades. The radius of this center of effort was 3.06 feet from the center, the resistance of a radial surface of rotation varying as the square of resistance from the center of revolution. The product of these two forces divided by 33,000 expresses the work done by the propeller in horse-power, and the reading of the brake determines the actual power applied to the propeller. The efficiency of the propeller was then determined by dividing the work appearing from the action of the propeller by the total power applied to it. From this it appeared that the efficiency at 155 revolutions was 70 per cent, at 200 revolutions 70.5 per cent, at 250 revolutions 75.2 per cent and at 300 revolutions 88 per cent. This may be considered an exceedingly satisfactory result. A thrust of 39.12 pounds was developed for an expenditure of 7.73 horse-power, which force is available at any time in any direction, for by revolving *a cam* which controls the *feathering of the blades*, it is possible to apply the thrust to drive the airship ahead or backward, to cause it to rise or descend without interfering with the speed or action of the engine.

Molecular Structure and the Origin of the Elements

CONCEIVED in the mind of ancient Greek philosophers, the atomic theory of the "grained" structure of matter was revived in 1803 by John Dalton to account for the fundamental law of chemistry, according to which every compound contains a definite and invariable proportion of its constituent elements. But the atomic structure of matter interests the physicist quite as much as the chemist; for is it not, according to the kinetic theory, the impact of gas molecules against the walls of the containing vessel which causes the gas to exert a pressure on these walls?

And we have long ago grown accustomed to look upon heat as "a mode of motion"—the dance of the molecules. But while these qualitative conceptions of the grained structure of matter are comparatively easy to comprehend, it has taxed the ingenuity of men of the highest scientific genius to develop the mathematical theory and to enable us to calculate the size of hydrogen molecules, of which forty-two million millions could be packed into the volume of a single blood corpuscle! And it is the triumph of experimental skill not only to have rendered visible to the eye that very dance of the molecules, but to have actually counted them one by one, taking advantage of the flash of light which an α-particle, a helium atom, gives out when it is shot out from a radio-active substance against a sensitive screen. And here the phenomenon of the grained structure of matter brings us face to face with another great problem. If there are different kinds of atoms, how came they by their several characteristic properties, the oxygen atom, for example, being invariably sixteen times as heavy as the hydrogen atom? Radium seems to hold a clue to this problem. It appears that some, at least, of the elements of higher atomic weight are continually undergoing disintegration, each atom of such element splitting up into others of lesser weight. And one product of the disintegration of radium is helium, as has been shown beyond doubt by Ramsay, Rutherford and others.

Have we then achieved the transmutation of the elements? Yes and no—yes, for radium is transmuted into helium and other products; no, for we have no control whatever over this excessively slow transformation.

This was but yesterday. To-day, if first accounts received prove authentic, we may answer our question with an unqualified "yes." For we read in the daily papers that Sir William Ramsay and Professors Norman Collie and H. Patterson have found newly formed helium and neon in bulbs originally containing hydrogen at a low pressure, and submitted to the influence of an electric discharge. This, then, so far as one is able to gather at the present moment, seems to be a definite case of transmutation (if not of creation) of elements under controlled and reproducible conditions.

Panama Canal Problem in 1638

To the Editor of the SCIENTIFIC AMERICAN:

When was a Panama canal first thought of and discussed? It must be a very long time ago, because I have just been looking through a very old and very interesting book of mine on commerce, published in 1638. It gives a map of each continent as then known, and mentions with particulars of each all the towns available for commerce in each. The map and descriptions of the towns in America are naturally rather primitive, but the following paragraph occurs with reference to Central America and is, I think, of special interest at the present time: "Peruana contains the southern part of America, and is tied to Mexicana by the Straight of Darien, being 10 miles broad, some hold the Spainards did once intend to cut this straight through and make it navigable, and thereby shorten the way to the South Sea, China, Mollucoes, but hitherto we have not heard that the same is any way attempted."

I thought your readers might be interested in this extract. H. ALLAN MORGAN.

Electricity as a Factor in Plant Growth

To the Editor of the SCIENTIFIC AMERICAN:

From time to time reports have gone out as to the effects of electricity on the growth of plants. Nearly all of these effects are alleged to have been observed in close proximity to lines carrying heavy currents, but as yet little has been done in the line of observing the effects of this all-pervading but mysterious force. It is possible and probable that electricity will yet be found to play an important part in the growth of vegetation, and who can tell but what, when it is once understood, we shall see it working as great wonders along this line as it has along others.

As an instance of the room there is for the study of electricity as it affects plant growth, I shall relate an experiment I performed the past summer.

I had noticed that nearly all weeds are well provided with points. I also noticed that such plants as sugar beets, cabbages, etc., that are not provided with points, are affected by the close proximity of weeds to an extent out of all proportion to the amount of fertility the weeds would rob them of, and they are much more seriously affected by the weeds than are other plants that are provided with points.

Now it is a well-known fact that the atmosphere is charged with electricity, and that electricity is most readily taken up by points. I went ahead on the supposition that plants take from the air the electricity it is charged with, and that in some way this electricity is necessary for their best growth. I supposed that the unusually bad effect of weeds on smooth-leaved plants might be due in a measure to the electricity the weeds robbed the other plants of. In order to test my theory, I selected a sugar beet and a cabbage and kept them well cultivated, but set up among the foliage a number of wires with sharpened points and left them there during the season. The result was that these plants showed a much smaller growth than others not so treated.

So far the experiment seems to have borne out my supposition that electricity does materially affect the growth of plants, and that the points on plants are important agents in gathering this force. If on further investigation this supposed law holds good, it would play an important part in the selection of varieties best suited to avail themselves of the electric energy. There are many things about plant growth and soils that are but meagerly understood, and this field would seem to be one of the most interesting and profitable for scientific study.

Ideal Automatic Train Control

To the Editor of the SCIENTIFIC AMERICAN:

Much valuable space has been given of late in your publications as well as others to the problem of automatic train control. For more than twenty years inventors have been working on this problem, and all along the same lines, that is to say, they try to provide means whereby a locomotive will be arrested automatically should it pass a signal set at danger.

The inventors have been working along this line because the heads of railways concluded that these disastrous accidents are due to the locomotive passing a signal set at danger. As in every other problem, the cause must be first found before the remedy can be applied. The inventors took the fact that "the locomotive passes a signal set at danger" as the cause. This is true, but why not investigate, and find the cause for the disobedience of a signal set at danger?

One of the railroads, about which there has been much discussion of late, gave out "specifications" setting forth the different characteristics which they expect an automatic train control to possess before they will consider the adoption of the same. Let me point out in this connection that even if this railroad company should find a system that will do all those feats set forth in its 'specifications,' this railroad company will be greatly disappointed if some time after the installation of such a system they should read in the 'extras': Big railroad wreck. Forty killed.' Let me point out now that a system that will arrest a locomotive only on passing a signal set at danger, might at times protect the trains and at other times it will not, and the chances are just as much one way as they are the other.

Assuming a "block" to be a mile long and a train stalled at the end of this block and assuming further that the mechanism operating the roadside device is in good condition, then any locomotive passing this roadside device, which was set to danger by the stalled train will be arrested and brought to stop in time enough to protect both trains. The same thing will happen if there should be a broken rail near the end of the block. But all this assumes 'ideal' conditions, i. e., all obstacles at or near the end of the block and the fact that these obstacles can just as well be at the beginning of the block is ignored. No system such as outlined above, could ever protect a train if the train be stalled 200 or 300 feet from the beginning of the block, nor could it protect the oncoming train if there be a broken rail within 200 or even 500 feet from the beginning of the block.

I do not think that a roadside device could be designed which would have a greater operating efficiency than the present-day automatic signals. Yet, perfect as these signals are, they do fail at times; and as perfect as such a roadside device may be, it will fail at times for the same reasons that the signals fail. The roadside device might be operated independently of the signal, yet it is possible for the track relay in both of the circuits to stick. Track relays often remain energized by stray currents which act the same as though the block occupied by a train were clear, and the track relay for the roadside device would not be exempt from such a condition. There are many other conditions that have not been considered in the search for an 'ideal' automatic train control, and in which cases a train control such as outlined above, would prove useless.

Thus it will be seen that the steps taken so far to solve this important problem are not altogether the right ones and the solution lies elsewhere, but it does exist, and I know it will come. MAXIMILIAN WEIS.

The Real Problem of the Mississippi

To the Editor of the SCIENTIFIC AMERICAN:

The question of protection of the Mississippi River bottoms from overflow and the matter of canalization of the river from various points has been discussed in documents, which some of the debaters on these questions may not have read. The idea of building reservoirs on the headwaters of the Mississippi, for example, was put into one of the first of the many studies of the hydraulics of the great river by Mr. Charles Ellet, who afterward won renown as a fighting man during the civil war.

The classic report of Capt. A. A. Humphreys and Lieut. H. L. Abbot submitted to the Bureau of Topographical Engineers of the War Department in 1861 is, of course, the original source of much information on the Mississippi. The abbreviated "Levee System" is, perhaps, the more familiar edition of this report. The report very clearly and apparently irrefutably exploded many of the theories which to this day crop up in any argument—the reservoir notion, for example. The army officers, after the manner of their kind, collated everything that had been discovered about the Mississippi and its tributaries. They even gave the then meager rainfall records from the far and scattered forts on the westward slope of the river basin, for instance—those forts where army men in the lonely routine of their daily lives, turned from the parade grounds to study birds and mammals and the lay of the land, enriching the literature of natural history—for instance, Capt. Bendire and Dr. Elliot Coues.

James B. Eads was the one, who after the civil war led in the combat against the Mississippi. His distinguished service led the SCIENTIFIC AMERICAN to propose that he be made president, and if he had been made president, the Mississippi River problem would not now be the brain teaser of all the solvers of the "How Old is Ann?" question.

The trouble with the Mississippi is that it fills up its channel with sediment, and the Government keeps right on building up the levees, till they are as high as the platform of the gallows of Haman, upon which they cut from under, and leave some people literally hanging to the grapevines. Mr. Eads said in effect that the levees should be built out from the highlands on the east and west side of the river valley perpendicular to the river channel. Then the overflow would be "eddied" and the sediment deposited among the trees. I have seen in a caving bank, and in a hollow tree places where sediment deposits were twenty feet deep—this in eddies of old. The purpose of the eddies, in pools made by earth dams across the bottom, perpendicular to the flow of the river, would be twofold: first, to build up the bottoms lands; second, to make the current swift enough to scour out its own bed and carry the sediment till it swung out into the eddies out of the channel or on to the Gulf. Incidentally, the dams would serve as refuges.

That is to say, the greatest and till then the only thoroughly equipped student of the Mississippi solved the problem upward of forty years ago; but so perverse are the gentlemen who take levee contracts, and so conservative are the gentlemen who have the power, that the obvious remedy and so far as any one has ever discovered, the only remedy, has never been applied except when the river itself roars through that tremendous folly, the levee system as built in recent years. I have not the figures here, but I question whether the floods last year were as great in volume as the previous floods, those of 1844 or of the early 80's.

I would suggest as food for reflection the fact that the streets of New Madrid were overflowed last spring for the first time; measurements of the river surveyors show that in four or five years the river channel in front of New Madrid filled in more than five feet. Below New Orleans it filled in nine or ten feet. No wonder that levees with only a margin of a few inches, or eighteen inches, fail to hold when the place where the current is swiftest is deprived of a depth of five feet of freeway.

Those who desire to verify these statements may do so by referring to the Report on Survey of Mississippi River, Document No. 50 of the House of Representatives, Sixty-first Congress, first session, and to the reports of the Mississippi River Commission, especially for the year that describes the flood of 1903.

In addition to this study of the documents of the Mississippi River, the gentlemen desiring to know what is the matter with the river and with the controllers of the river should by all means go down the Mississippi and take jobs on the mattress work, perhaps pull an oar for the river surveyors—I think they use motor boats now, but when I was down there they rowed—and listen to the things the men on the jobs say. A few hours in a levee camp, sitting around the commissary stove along toward the end of a levee contract, will add interesting supplementary evidence to that found in the documents. Sometimes it gets into the documents, for none writhes more under the political phase of this matter than the honest officers. It was on the Mississippi job, for example, that the army men waited for the hour when the nation would call them to the honest effort at Panama. Consider their feelings when they sent dredges to Wolf River at Memphis year after year to take out sawdust.

The men who conquered Panama could conquer the Mississippi River; let no one doubt that. But just as long as the men on the Mississippi River job are held to the whims of congressmen and senators and levee boards, and even to the demands of cotton planters who own three miles fronting on a Government levee, just so long the Mississippi River shall go on its course filling up its bed with 200,000,000 cubic yards of material, while the Government keeps on piling up its little levee system on both banks, doing very little permanent or adequate work.

On page 40, "Survey of the Mississippi River" (1909) is a little table. It tells how much the annual cave is in various river bends. The average from Cairo to Donaldsonville is 9½ acres to a depth of 93 feet, or 1,003,570 cubic yards. The distance by river is 885 miles. That is 850,000,000 cubic yards of material washed down stream. During nine months of the year floating sediment to the quantity of 187,000,000 cubic yards came down the Missouri into this lower river. Besides this floating sediment, the river of mud, sand and gravel at the bottom of the water must be reckoned with. In all the Missouri is dumping fully 300,000,000 cubic yards into the Mississippi, where the Government is heaping up three or four million cubic yards of dirt a year, to counteract the effect of this channel deposit.

Why not bring the men who dug the Panama Canal back to the Mississippi and give them the opportunity to assail their ancient enemy, unimpeded by the contemptible politics that has restrained the impatient men who know what to do and would do it to the everlasting advantage of the country? When those men were beyond the reach of the picayune influences, and were left at least sufficiently alone in their work they conjugated the verb To Do.

They are the men who know; they don't own cotton plantations, nor boom swamp lands, nor sit on railroad directorates, nor speculate in sugar and rice; they see their duty, and the one thing in all the world that they would rather do is their duty. All that stops them is the—we all know, and the more shame to us since we do know.

Give them a chance!

Little Falls, N. Y. RAYMOND S. SPEARS.

The Art of Making Bronze Statues

From the Raw Clay to the Finished Figure

By C E Fairbanks

THE artist who portrays his conception in bronze encounters many obstacles which his brother of the palette and canvas never has to contend with. Among other difficulties is the fact that the work of the former has to pass through several hands other than his own before completion whereas the work of the latter is begun and finished by his hand alone.

In giving expression to his conception the sculptor frequently works it up from a minute model in the rough which but faintly suggests the portrait that is to be, to sizes larger and more detailed until finally the model for exhibition is finished. This model while expressing all the details may be much smaller than the desired size of the final work—especially if this is to be life size or heroic. For working material the sculptor uses either wax, modeling clay, or some special composition which in addition to being plastic will retain its shape indefinitely and support a very considerable weight. To avoid excessive use of clay but principally to stiffen the figure a skeleton framework is constructed and is known as the armature. Fig 1 shows the armature for the whaleman with poised harpoon—in the New Bedford (Mass.) Whaleman Memorial by B. L. Pratt. A pointing machine consisting of a vertical stand with a multiplying horizontal arm is used to transfer from the accepted model and locate on the armature such points as nose, chin, knees, etc., as this framework is assembled. The clay is then plastered on roughly and afterward shaped to a finish as is shown in the view (Fig 2) of B. L. Pratt's studio, at the left being the figure of "Art" for the Boston Library with the clay roughly plastered on the armature, in front of it being the pointing machine; at the right Mr. Pratt is finishing off the figure of "Science," while in front stands the woman model.

After all finishing touches have been put on the sculptor turns the clay portrait over to the plaster-cast men, who mold about it a shell of plaster of Paris. This shell is then removed by inserting sharp metal pieces about 4 inches square along certain lines depending upon the contour of the figure, and by this means splitting the shell into sections, which enables it to be removed entirely. The shell is then reassembled, and as this progresses a rough framework not unlike the original armature is built up inside of the reassembled shell, excelsior being used to fill any openings in the framework. To prevent the sections pulling apart the entire shell is either bound up securely with wire or is encased in sand. Liquid plaster of Paris is then poured in through an opening at the top and the shell filled—the interior framework serving the same purpose as the armature of the clay model. After removing the shell we have in plaster of Paris a duplicate of the original clay portrait. For proper molding in the bronze foundry it is invariably necessary that the plaster cast consist of from two to twelve or even more parts as the contour of the figure may dictate, that is the head, one or both arms, the base and other parts must be removable so that they may be molded separately. This end is attained in one of two ways. When the plaster cast is made, those members which should be removable are made separately and fitted into a socket cut into the body of the figure, or else at the foundry these members are sawed off, a protrusion is built on the end of each member and made to fit into a socket cut into the body at the point of amputation, thus forming, when assembled, a socket joint. In making the plaster cast of Lincoln (the finished bronze is shown in Fig 11) the left arm, the right arm, the legs, and the head are all removable. In the accompanying illustrations the manner in which the various pieces are separately molded is very clearly shown.

When completed the plaster cast is then delivered to the founders, and here the requirements are so exacting that a combination of skill and patience is necessary at every step. In the foundry the molding is done in dampened sand imported from France, which is not unlike very fine clay in texture and can be packed quite hard. It has the quality of retaining the finest lines of an impression, and will neither lose them nor burn when in contact with molten metal. In the simplest patterns the containing box for the entire mold is made in two halves—an upper and a lower—and is known as a "flask." In the complicated molding of a statue the flask may consist of any number of iron sections held together by clamps, each section supporting some portion of the mold.

Fig 4.—Packing in sand and building up the flask.

After separating the plaster figure into its various component parts they are dusted with soapstone. Starting with the body of the figure or largest portion, it is laid in that position which enables it to be most easily withdrawn from the sand. The molding sand is packed solidly and carried as high as the contour of the figure will permit of easy withdrawing. The surface of the sand is then dusted with plumbago or similar substance to prevent adhesion of the succeeding layer, an additional section of the "flask" put in place, sand again packed in and carried higher on the figure, as shown in Fig 4 and so on until it is entirely covered. It invariably happens that the surface of the figure is so complex that blocks or sections of the sand have to be arranged to move horizontally away from the plaster cast when disassembling the mold. In Fig. 4 the section in front of the face is of this type. Also, the removable sections of the plaster cast are either molded separately, or put in place as the molding of the figure reaches that point, as in Fig 7, where the head of the statue has been added.

In spite of the fact that the sand packs hard and sustains quite a weight it is necessary, when the surface of the mold is of considerable area and irregular in shape, to stiffen it with a framework of iron pieces roughly fitted over the outline of the surface and wired together as shown in Fig. 8. The sand is then packed in place and the form completed as in Fig. 9. Fig. 8 also shows the line of separation between the upper and lower molds.

After the entire plaster cast has been

Fig 5.—Lincoln torso immediately after casting

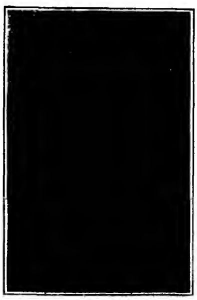

Fig 6.—The torso after superfluous metal has been cut away

covered or molded, it is then necessary to remove every section of the mold in order that the figure may be taken out. Since a solid casting would add both unnecessary weight and cost without in any way adding to its appearance, it is made hollow. To do this the various sections of the mold are reassembled, and as this progresses the space formerly occupied by the figure is packed with sand, forming, when completed, what is termed the "core." The same reason that applies to any other large section of the mold requires that a framework of iron with projecting ends for supporting and handling be built inside the hollow space as shown in Fig. 8. When the "core" is completed the mold is once again taken apart and the "core" removed. It is to be remembered that this entirely filled the space formerly occupied by the plaster cast figure, hence, in order to provide space for the metal the entire surface of the core is shaved away to a depth of about one quarter inch, thereby allowing this amount of space between the core and the mold, as can be distinctly seen in Fig. 9, and it is into this space that the molten metal will flow.

The projecting pieces of the iron framework of the core, which rest upon the mold body, hold the core away from the sides of the mold. These projecting pieces can be seen in Fig. 9, where they serve the additional purpose of handling the core. A vertical hole or passageway is provided starting from the bottom of a reservoir on top of the completed mold and connecting with numerous horizontal runways at different depths which reach various parts of the mold so that the molten metal may reach all points of the mold as soon as possible. Some of these runways can be seen in Fig. 9.

The slightest trace of moisture in the core would become converted into steam and ruin the entire figure when the molten metal came in contact with it, hence, to avoid this the various sections of the core are loaded on a car and carried into an oven where for 24 hours they are kept at a temperature of from 500 deg. to 700 deg. Fahr.

Then for the last time all portions of the mold and core are carefully reassembled, vents are provided for any gases generated, the sections of the "flask" are securely clamped together, a clay lined reservoir is placed on top so that a large amount of metal may be collected before it is allowed to run into the mold, and all is ready for the crucial moment when the powerful crane will lift the big iron bucket holding 2,000 pounds of molten bronze and amid pent up excitement will begin the pouring which will determine whether success or failure will crown the painstaking effort of weeks and months.

Fig. 3 shows the completed flask with reservoir all ready for the pouring. Bronze is an alloy of copper, zinc, and tin. For statuary work the mixture usually consists of 90 per cent of copper, 3 per cent of tin and 7 per cent of zinc although the proportion of tin and zinc is varied to suit conditions. Any of several colors may be given bronze by proper acid treatment, although the natural color gives a better effect, and is generally used. When the metal has cooled sufficiently the sand is broken away from around it, the casting removed, thoroughly washed, and the core removed by washing and cutting. The figure has somewhat of an uncouth appearance, as seen in Fig. 5, in which the projecting parts of the core are seen and the runways are represented by the grapevine effect. All superfluous metal is cut away, an acid bath is given for further cleaning, and the bronze figure now has the appearance seen in Fig. 6. It is now carried to the finishing room, where all of its parts are assembled and permanently fastened in place, any seams being welded together with pneumatic hammers. After a careful inspection and retouching the statue is completed as seen in Fig. 11. It is now ready for its final resting place where it will remain through generations to come a perpetual monument and reminder of the greatness which once helped make history.

By far the greatest number of statues are of army officers; statesmen come next, representatives of the pulpit are sometimes perpetuated in bronze, and away down the list come the navy officers. This may be because the greatest number of our important battles up to and including the civil war were fought by the army, hence the greater number of prominent officers are of the army, or it may be that we have been somewhat slow in perpetuating the memory of our none less valiant and important heroes of the navy.

Generating Current at the Mine

THE cost of power for lighting and manufacturing purposes depends generally on the cost of fuel, and the cost of fuel in most cases is determined by the freight rate, or transportation charges from the point of production of the fuel to the center at which the power is required. Successful efforts have been made in Nova Scotia to transport power in the form of electric energy from a colliery to neighboring centers, thus avoiding freight rates or reducing these rates in an amount equal to the loss in electrical transmission plus interest on cost of transmission line.

At Chignecto the central station is located and the district is supplied from this point. The central station as originally equipped contained one 500 kilowatt generator, direct connected with a vertical center crank cross compound engine running at 100 revolutions per minute.

This plant was installed primarily to make a market for some unsalable refuse from the colliery, but the success met with was so marked that additional units were installed. The plant now has a capacity of 1,500 kilowatts and is running with an overload, while plans are being prepared for installing an additional 1,000-kilowatt unit, contracts having been signed for the disposal of the greater part of this additional power.

The power station is located one hundred feet from the bankhead at Chignecto Colliery, and conveyors are so arranged that the fine culm which passes through the screens and crushed refuse which is picked from the screened coal in passing over the cleaning belts, is conveyed directly to overhead storage pockets in the boiler room of the power plant. This fuel contains 23 per cent ash and is fed by gravity into mechanical stokers.

The current is transmitted at 11,000 volts, 3 phase, 60 cycle, and is utilized at Amherst, eight miles from the central station, for general factory purposes and the entire lighting of the city. At Nappan the gypsum quarries operate their derricks and pumps.

Collieries at Joggins Mines, fifteen miles from the central station, are operated mostly by electricity, and the ventilating, pumping and coal cutting machinery are all motor driven.

River Hebert is a thriving farming community, the farmers of which utilize the cheap power available to their own advantage for milking, separating, churning, etc. At the other points touched by the transmission line the power is chiefly used for lighting purposes.

This project has been brought from its small beginning to its present successful state under the direct supervision of G. B. Burchell, a consulting mining engineer of Montreal, Canada.

American University in Siam.—Under the auspices of the American Presbyterian Mission in Northern Siam a university is in process of development at Chieng Mai. It is expected to absorb the Prince Royal's College as the college of arts, in addition to which there will be faculties of sciences, medicine, and theology.

Parabolical Overhead Wiring for Electric Roads

By Owen M de Musnick, C.E., E.E.

THE construction of overhead wiring for electric traction has undergone considerable alterations during the last few years alterations which were to be expected owing to the great extensions of railways and tramways and to the increasing speed The existing construction did not meet the latest requirements, and the chief factors which led to the reconstruction can be considered as the following

I The application of high tension alternating current for traction purposes.

II The necessity of a minimum sag of the conducting wire at high speeds to insure an even contact of the bow (trolley)

III The necessity for suspending the conducting wire in a non rigid manner due to the fact that each rigid point jars the contact bow (trolley) causing it to spark also imparting a trembling motion to the bow (at high speeds) resulting in a series of sparks.

To meet the above requirements it was needful to provide a new means of hanging the conducting wire above the track This was found in the catenary system which permits of the conducting wire being suspended at short intervals and in quite a yielding manner Such a system exists in Holland on the lines Leiden Katwyk Noordwyk and Rotterdam The Hague-Scheveningen The last mentioned line possesses the peculiarity that the influence of the temperature is neutralized by means of weights which give a constant strain to the wire This conducting wire is, of course suspended in a movable manner The parabolical carrying wire, with the parallel wire above the conducting wire, as used on the New York, New Haven and Hartford Railway, are not movable, they are thus subject to the influence of the temperature, lengthening and sagging in hot weather and shortening with increased stress in cold.

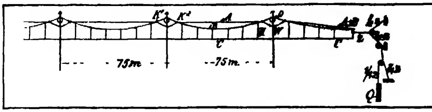

Diagram showing the method of straining the cables so as to prevent sag

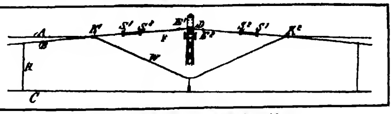


Detail of the support at one of the bridges.

To avoid this drawback a system was contrived by the A E G Company by which all wires are made movable

During a number of years they have made different trials along these lines on their experimental railway at Oranienburg, and have succeeded in constructing a system that was adopted by the Prussian State Railways. In 1910 the line Dessau Bitterfeld (steam railroad) was partly equipped with this system, the other part being carried out by the Siemens Schuckert Company (the same system as the Rotterdam The Hague-Scheveningen which was constructed by the same [S. S W] company)

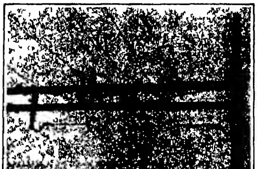
Dessau Bitterfeld is only a trial line, as plans are made to electrify the whole steam road from Magdeburg Leipzig and Halle. This extension will be very important, as the newly constructed part is only 27 miles long and rather too short for making long distance trials at high speeds.

In the accompanying drawings of the A E G system, showing three spans of the overhead line and the method of suspension on a cross girder A is the strain wire, B parabolical suspension wire C conducting wire H vertical suspension wire K_1 and K_2 are clutches, W is the loop formed by A and B passing below the cross girder F is a flexible wire to which the insulators S_1 and S_2 are attached This wire connects the clutch K_1 with K_2 and brings the strain over from one side to the other as the loop W is hanging loosely This flexible wire F is insulated between the insulators S^1 S^2 and rests on the diabolo insulator D on the cross girder Two notches E_1 and E_2 are fixed on each side of the insulator D, which prevent the flexible wire F from moving too far to the right or left under the influence of the temperature Galvanized clutches are used to join the wires together where necessary, as no connection was made by soldering

The insulators are so made that in case one of them breaks the whole system cannot fall as the two wires are looped inside the insulator The strain wire A is provided to assure a regular stretch of the parabolical carrying wire over the whole length from the fixed point to the weights. This strain wire, of course has very little sag The clutches K_1 and K_2 join the strain wire and the parabolical suspension wire at each suspension point on the mast, bringing their strain over on the flexible wire F The loop formed under the cross girder by the two first mentioned wires is necessary in case an after regulation of one of the wires is needful The working of the system is as follows

When the temperature is increasing, the parabolical carrying wire B will expand, thus increasing the sag or in other words decreasing the strain The strain wire A will expand to about the same extent, being made of the same material (galvanized steel cable) its strain will also decrease, and, as it has very little sag, its strain will decrease considerably more than that of the parabolical wire The weights at one end pull with a constant strain, and thus stretch both wires until the strain is balanced, when the drops will be exactly the same as before since for a certain constant strain there is always a certain constant drop. By a decreasing of the temperature an opposite action will take place The same happens to the conducting wire, as it is also connected to the same weights at the end. Near these weights is a lever P to which the three wires are joined, and a flexible wire bringing their stresses over to weights on the mast This lever is necessary because the strain wire and parabolical wire are made of steel, while the conducting wire is made of hard bronze. These have different temperature coefficients, which this lever neutralizes.

To start the building up of the system little hooks are fixed to the masts at *each side of the railroad (about two meters above the ground)* On these hooks provided with wheels the flexible wire F (already fitted complete with the insulators and clutches) is laid, and the strain wire and parabolical wire are fixed to this flexible wire and the required drop of both wires regulated. This drop can be measured by means of a dynamometer (measuring its strain), but it is easier and quite exact enough to find it in the way described below A little wooden post is erected in the middle between the two masts, three movable hands are fitted to this post. The top one is level with the disk on the mast, the other two hands giving the theoretical drop of the two wires. When this is finished complete section from one pair of weights to a new pair (distance of about 1000 meters), is ready The vertical suspension wire can also be fitted The conducting wire is hung on these wires (after being stretched on half its normal strain) When the whole system is ready it is pulled up by block and tackle over the whole length of one section and placed on the diabolo insulator in the center above the track It is always necessary, of course to inspect the system after it has been placed in the proper place, by means of a tower wagon.



Details of one of the bridges, showing method of straining the cables.

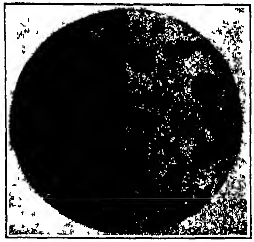
Constructing the line at the ground before hoisting in place.

A Comparison Microscope

By Dr Wilhelm Thoerner

THE manifold demands and wishes of workers in every field of scientific and medical research have been met by instrument makers, very successfully, as a rule, by improvements in the mechanical and optical construction of the microscope and its accessories. It is the more remarkable therefore that no instrument has come into general use for the simultaneous observation and direct comparison of two microscopic objects. Such an instrument which may be called a comparison microscope would render very valuable services in a great many scientific investigations. In testing articles of food for example it would often be

(Concluded on page)



Comparison of two specimens of diatom plankton

A comparison microscope.

The Mono-rail Sled

A NEW type of sled has put in an appearance recently which should delight the heart of every small boy. The object which will first catch his eye is a steering wheel, a real live steering wheel, just like that of an automobile, and it controls a steering runner placed in advance of the two main runners. But even more interesting than that is a fourth runner placed between the main runners. Ordinarily this does not come into play. But after the young coaster is well started down the hill he pulls the steering wheel toward him, depressing this fourth runner, and raising the entire sled upon it so that he continues to glide down hill on two runners, arranged in tandem. This reduces the friction surface, enabling him to outstrip his rivals on the more clumsy type of sled. A certain amount of skill is required to maintain the balance on the center runner, so that the sled will run like a bicycle, and this adds interest and excitement to the sport.

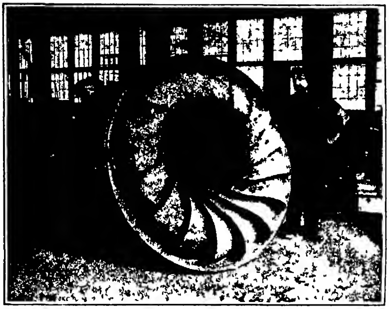
Readers are invited to contribute photographs of novel and curious objects, unique occurrences and ingenious contrivances. Such as are found available will be paid for promptly.

A "mono-rail" coaster

Balanced on tandem runners.

Turbine Casting for the Gatun Power House

THE accompanying illustration shows one of the three turbine castings recently made at Hartford, Connecticut, for the power house at Gatun, Panama. The turbines will take water from the great lake formed by the Gatun dam and will drive electric generators to supply the power for operating the gates and towing the vessels through the locks and also for lighting the Canal Zone. The turbines will have to develop 4000 horse-power. The castings are made of a composition of copper, tin and zinc in the proportion of 88, 10 and 2. The alloy is required to show a tensile strength of 30,000 pounds, an elastic strength of 15,000 pounds, and 18 per cent elongation. The castings weigh a little under 7,500 pounds. It will readily be appreciated upon examining the illustration that some very intricate dry sand core work was necessary to produce these wheels. The vane cores, of which there were sixteen for each of the three wheels, weighed a little under 700 pounds each, and because of their peculiar shape, they were exceedingly difficult to set.



Intricate turbine casting for the Gatun power house

Benvenuto Cellini's Portrait of Himself

THE rear of the helmet of the famous statue of Perseus at Florence is cleverly designed to represent a face, with a beard formed by the curling hair beneath. Although this face has been known to exist for some time no attention has been paid to it. Recently, however, an antiquarian named Annibale Benedetti discovered the face, and was struck with its marked resemblance to Benvenuto Cellini who made the statue. It is a curious fact that no reference to the portrait is found in the state archives or in any of the descriptions of this piece of work, nor even in Cellini's own memoirs of his masterpiece. The statue was ordered by Cosimo di Medici, and the theory has been put forth that being jealous of the glory that might come to Cellini, he would not permit the sculptor to place his name upon the statue. On the other hand, Cellini being a very vain man, could not give to the world this masterpiece, which took him nine years to complete, without identifying himself with it in some way. Hence, he adopted the daring and novel expedient of actually carving his own likeness upon the statue, so that for all future time there would be no doubt of its authorship.

Portrait of Benvenuto Cellini, discovered on the helmet of his famous statue of Perseus.

The Sleigh of the Desert

A CORPORAL in the French army in North Africa has devised a peculiar machine particularly adapted for travel over the sand wastes of the Sahara. The machine is a cross between an automobile and an aeroplane, and has been dubbed the "sleigh of the desert." The construction is very light indeed. It is mounted on broad tired pneumatic wheels, but is driven by an aeroplane propeller. It is so light and its bearing surface is so great that it will ride over the sands without sinking, leaping over light depressions and climbing the steepest sand dunes. There is a decided advantage in using an air propeller, for then the drive of the machine is independent of its traction. In the loose sand of the desert it would be rather difficult to propel a machine after the manner of an automobile. The accompanying photograph, which is published by courtesy of *L'Illustration*, shows the odd machine upon its arrival at Toujourt having carried Gen. Baillond over a distance of about 130 miles. The peculiar vehicle is named La Souterelle or the grass-hopper because of its peculiar hopping flight over the irregularities of the desert.

The "grass-hopper" coach of the Sahara.

Fish Killed by Frost and Storms

IN *Symons's Meteorological Magazine* the Rev. D. C. Bates, dominion meteorologist of New Zealand, tells of some curious effects of atmospheric disturbances on fish. A deep-sea species known as the frost fish (*Lepidopus caudatus*) is found lying dead on the shores of the South Island of New Zealand during and after severe cold weather. It is a long ribbon-like silvery fish of delicious flavor and men scour the sands at night to find it. These fish rise from very great depths and apparently are killed by the bursting of their air bladders rather than by the cold; yet their coming to the surface seems to be connected with the weather, especially with anticyclonic conditions.

After severe storms the coasts of New Zealand are often strewn with tons of dead fish of many species. A correspondent of the author writes in regard to such an occurrence at Island Bay, Wellington, on July 18th, 1912: "This is not the first time, nor the tenth time, that fish have been landed on the shores of Cook Strait in precisely the same fashion, in every case subsequent to a storm. Therefore we must look for the cause in the storms, unless it is that storms only produce what we call fumes by stirring up the bottom of the sea. Immediately offshore we have comparatively deep sea, inhabited by fishes which are not usually met on the immediate coast line. If from any cause during a high storm deep-sea fishes lug close to the land, then it only requires a very heavy sea in which waves strike the bottom to involve the fish, rush them ashore, and kill them by hundreds."

After the storm of July 18th mentioned above, great quantities of the dead fish—ling, hapuka, hake, etc.—were gathered and brought into Wellington. On another occasion some thirty years ago the beach at Okarito on the South Island was strewn for seventy miles with fish of all sorts and sizes.

How to Wax Old Unpolished Floors

TO wax old floors that were never polished the following method is good. The floors should first be washed thoroughly and then when dry coated with some floor oil such as linseed oil. This should be at once rubbed with sawdust, which removes all surplus oil and polishes the floor. After this any wax may be used according to its directions, and then after a weighted brush is used the old floors will be as slick as new oaken floors. After this they should only be washed with gasoline.

A Bill Providing for a New Patent Office

ON January 17th, 1913, Mr. Bulkley introduced a bill providing for the construction of a Patent Office of the United States. The sum of $4,000,000 is to be appropriated out of any money in the Treasury not otherwise appropriated for the erection of a fireproof building. It is very doubtful if the bill will be taken up during the present session. Everyone at all familiar with present conditions in the Patent Office will recognize the necessity of the new building.

Simple Patent Law; Patent Office News; Notes on Trademarks

Recent Improvements in Machine Tools—II

[IT has often been said, and rightly so that the perfection to which metal working has attained is one of the miracles of modern times In many factories throughout the country the various pieces are turned milled, sawed, planed or ground in such quantities at such speeds and with such unfailing accuracy as to command the admiration of the observer Yet in spite of this perfection there always seems to be room for further improvement This is the second of a series of brief articles on recent improvements that have been made in machine tools EDITOR.]

IN bevel gear cutting machines it has long been the custom to tilt the cutter carriage to the proper angular position desired

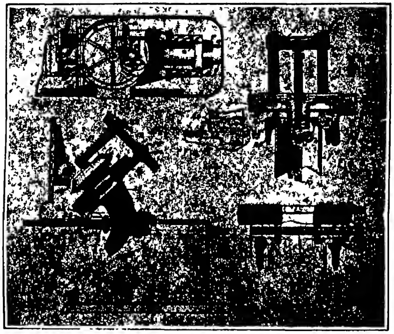
The disadvantage of this proceeding has been that such a structure lacked the proper rigidity for heavy cutting—a disadvantage which has been particularly noticeable since the advent of high speed steel cutters. This lack of rigidity is due to the mounting of the reciprocating cutter carriage upon the angularly adjustable slide and the circuitous route by which the motion is transmitted from the primary mover to the cutter spindle and feed screw

A recent patent granted to W F Zimmerman of Newark, N J, shows a marked commercial advance in the art of cutting bevel gears. Instead of tilting the cutter carriage, the patentee provides a work table which is capable of being tilted to the proper angle This table is so constructed that the strains imparted thereto by the cutter are taken by a base of rigid construction

The advantages of this device are at once apparent In the usual constructions where the cutter is adjusted, there are three sliding surfaces necessary—two for the cutter and one for the work table But by adjusting the work table, only two sliding surfaces are required—one for the cutter to reciprocate thereon and one for the work table Then too a less complicated drive necessary to rotate and feed the cutter is required It also eliminates the additional means required to control the reciprocating movements of the cutter slide and the indexing of the blank the index drive being practically the same as usually found in ordinary spur gear cutting machines.

As seen in the figures, an adjustable slide 2 is provided with clamps 25, operated by handles 26 so that the slide 2 can be firmly secured to the frame 1 Hinged to one end of the slide 2 is a tilting bed 3 having rotatably mounted therein a work table 4. A work arbor 6 is secured in this work table by means of a differential nut 5 and centers the bevel gear blank 7 Depending from the center of the tilting bed 3 is a segmental arm 9 having a worm wheel segment 10 This arm is secured to the slide 2 by means of a bolt 56, its outer periphery being rigidly clamped by means of a clamp 57 to a finished portion within the aperture of slide 2, through which the arm passes

The tilting bed 3 and the bevel gear blank 7 are adjusted to the proper angular position by the worm 11, rotatably mounted in the slide 2, engaging the worm wheel segment 10 On one end of the worm 11 is a helical gear 12, held in position by means of a nut 13 which engages with a helical gear 14 This gear 14 is slidably keyed upon and rotates with the splined segment adjusting shaft 15, and is held between the bearings 16 in the slide 2 The forward end of the segment adjusting shaft 15 projects beyond the frame 1 and is provided with a graduated dial 17 and a square end 18 to receive a crank handle The ratio of the worm wheel segment 10 and worm wheel 11 and helical gears 13 and 14 is such that for each turn of the segment adjusting shaft 15, the bed 3 is adjusted one degree indicated by the dial 17 graduated to read in minutes.



In this bevel gear cutting machine, a distinct improvement has been effected in machine tools. Instead of tilting the cutter carriage, the patentee provides a work table which is capable of being tilted to the proper angle.

As seen in Fig 5, a graduated segment 10, reading in degrees, is secured to the bed 3 in connection with a vernier scale 20 reading in tenths of a degree to indicate the exact angular position of the work at all times.

The work table 4 is rotatably mounted in the bed 3 and is provided with T slots 21, to secure the blank to the table The index wheel 22, which rotates the work, is arranged upon the periphery of the work table 4. The work table 4 is supported near the outer periphery by a circular bearing 23, arranged in the bed 3, and is held thereto by a circular plate 24 secured to the bed 3. This plate 24 is provided with a circular groove to form a channel for the cuttings and the lubricant to lead them into the base of the main frame. The plate 24 also serves as a guard to protect the index wheel from chips and dust.

The index wheel 22 is rotated by an index worm 27, rotatably mounted in an adjustable bearing 28 on the bed 3. The bearing 28 is adjusted toward or away from the index wheel 22 by means of the handle 30 A stop-screw 31 is provided in the bearing 28 to gage the depth of engagement of the worm 27 and wheel 22. A helical gear 32, engaging with a second helical gear 33, is mounted on one end of the index worm 27 The gear 33 is loosely mounted upon the hinged shaft 34, passing through the lugs 35 and 36, and the lug 37 between the lugs 35 and 36 is supported by the ways of the main frame 1 The helical gear 34 is rotated by a helical gear 38 rotatably mounted in a bearing of the slide 2. This arrangement of helical gears provides for transmitting a rotary motion from the helical gear 38 to the index worm 27, independent of the angular position of the worm 27, and for the disengagement of the index worm 27 from the wheel 22 in all the angular positions of the worm 27

The cutter carriage 48 with rotary cutter 49 is reciprocated vertically by well known means.

When the work has been adjusted to the proper angle, the slide 2 is adjusted longitudinally toward the cutter carriage 48 by means of the screw 46, the end 47 of which is adapted to receive a crank handle The amount of adjustment is indicated by the dial 50 graduated to read in thousandths of an inch After the work is secured to the mandrel 6 by means of the nut 8, the projecting end of the mandrel 6 is supported by a triangular arm 51, slidably arranged upon two posts 52 and clamped thereto by means of the handles 53. The posts 52 are slidably mounted in the bearings 54, provided in the bed 3, and are clamped to the bed 3 by means of the bolts 55.

Shall we permit the Oldfield bill to become a law and destroy this monument?

The Oldfield Bill Cartooned

THE accompanying cartoon, reproduced by courtesy of *Judge* from the columns of that weekly, tells its own story Readers of the SCIENTIFIC AMERICAN who have followed the attempt to pass a measure which cannot but have a destructive effect upon our patent system, and which must inevitably discourage invention will appreciate the graphic truth of the cartoon *Judge's* title for the picture evidently inspired by a resolution addressed by the Inventors' Guild of New York city to President Taft, read

Invention has contributed the greatest blessings of civilization and for America has laid the ground work of our wonderful industrial prosperity The American patent law, by its liberality to inventors, has fostered the inventive faculty and made us the foremost inventive people. If we value future progress and continued prosperity, we should change our patent laws only after the most scientific and searching study, and only upon the most conclusive grounds."

A Non-refillable Bottle.—In patent No. 1,046,757, to Charles C Fine, assignor of one half to Jacob W Fine, both of Nanticoke, Pa., is shown a bottle in which there is provided a longitudinal passage parallel with the neck outlet and opposite said passage is another longitudinal passage communicating with it through a lateral opening and a second longitudinal passage contains a ball which controls communication with the interior of the bottle to prevent refilling and may be unseated to permit the contents of the bottle to be dispensed.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Pertaining to Apparel.

BELT BUCKLE.—M GREENFELD, care of Ralph B Ittelson 170 Broadway New York N Y The invention relates to improvements in buckles and particularly to belt buckles and has for an object the provision of an improved catch or interlocking structure adapted to be readily engaged and disengaged but firmly held in place when engaged.

GARMENT STIFFENER.—ROXANNA A HAMPTON 23 W 24th St Manhattan N Y N Y This stiffener is more especially designed for stiffening the yokes of ladies dresses and waists such as open along the back and arranged for convenient insertion in the yokes and sufficiently pliable to readily conform to the shape of the wearer with a view to give the desired stiffness to the yoke without rendering the garment uncomfortable

Of Interest to Farmers.

YOKE.—J LLORET and J GIMENEZ Calle Colon No 2 Habana Cuba For the purpose of enabling an animal to more easily carry a load attached to a yoke use is made of a main stem adapted to turnably engage the shaft or tongue of a vehicle a main bearing body mounted to swing on the main stem auxiliary bearings on the main bearing body and head bows mounted to swing on the auxiliary bearings

Of General Interest

FENCE POST.—R F CARPENTER, Bandon Ore The invention provides a one piece post which may be driven directly into the ground and which does not require tamping Also provides a post with means for holding the fence wires securely but in such a manner that they may be released from the post when desirable

PLANT PROTECTOR.—W G COWART Nocatee Fla This protector is formed of fixed and movable parts consisting of panels and supporting stakes A series of oblong panels is supported in fixed position inclined, say 30 degrees to the vertical by means of stakes set in the ground and inclined in opposite directions, their upper ends or heads being connected with the top or ridge bars of the panels, the latter being placed near and parallel to the row of plants needing protection Another portion of the protector is composed of a series of adjustable panels, and a third series may be employed and adapted to extend over the plants, or fully folded back for exposing the plants Mr Cowart has invented another protector formed of two oblong panels secured together rigidly at an angle to each other whereby the device is adapted to be applied over and protect plants and with means for supporting the protector when turned on its side so that it is held constantly in position for replacement over the plants.

COMPOSITION OF MATTER TO BE USED AS A FLEXIBLE COVERING.—F M GUSCH BAUER care of W O Fahl Am Flexible Slate & Covering Co Milwaukee Wis This invention relates to a covering material to serve as a substitute for slates tiles and other forms of water and acid proof coverings and linings An object of the inventor is to provide a flexible covering impervious to acids and alkalis, of a water proof and air proof material for use as a roof covering or in any locality where it is desired

DEVELOPING TUBE.—J F WALLACE Varna, Ill The invention provides a means whereby photographic films may be developed in daylight The device is convenient for carrying without liability of injury Developing means is provided that may be conveniently manipulated and which will insure that the film is effectively subjected to the developing fluid

FLEXIBLE SLED.—J C MINIER Ridgway Pa. An object here is to provide a device which is more easily manipulated than the ordinary flexible sled in that it has greater leverage upon the flexible runners. It costs no more than the ordinary sled for rendering the present flexible sled more susceptible to guiding influences.

LIFTER AND CONVEYER FOR INVALID BEDS.—J GERMAN Richland Center Wis This invention relates more particularly to the combination of a bed an auxiliary support adapted to be positioned upon the bed to receive the patient and means for moving the support in a plurality of directions and for removing it entirely from the bed to a point remote from the same the means serving to hold the support in different operative positions when it is removed from the bed

DRY CARTON.—A TAYLOR 15 E 42nd St New York N Y Among the principal objects which the present invention has in view are to provide means for preventing injury to articles by moisture while in storage or transportation and to provide a simple efficient and economical means for deleting the moisture from cartons or other such devices. The cartons may be used for holding tennis balls, cigars, candies, and a wide variety of other materials.

DRINKING CUP.—C. A BRYANT, Passaic N J This cup is made of paraffine paper in

the form of the frustum of a cone and is made of a single sheet of paper doubled up and having the sides connected with each other the bottom being flat and upon which fold ears fastened in place by a separate strip glued thereto and overlapping the ears.

LOCKET—J NEDERLAND, 276 Fifth Ave., Brooklyn, N Y To provide a hinged frame shaped to prevent buckling when the locket is made of light material to provide a hinged construction shaped to the contour of the locket, to provide a frame for the locket having the glass and picture frame formed integrally therewith to form an interior snap integrally constructed from one portion of the frame to engage the other portion, such are the principal objects of Mr Nederland's invention

CHANGE LETTER SIGN—W ELLISON Roosevelt, N Y The invention consists in securing between overlaying areas of open mesh wire gauze opaque letters assembled and arranged to form a reading sign the contrast between the opacity of the letters and the transparency of the gauze imparting an aerial and unsupported appearance to the sign. A simple means is provided for binding the over layed gauze on the interposed letters.

SAFETY BOTTLE HOLDER.—T ZARRANAS care of A. M Marters, 120 Grand St. Brooklyn, N Y This holder is arranged to permit the milkman readily to place a bottle of milk therein and prevent unauthorised persons from removing the bottle surreptitiously from the holder The holder is provided with a sliding cover which may readily be opened by the milkman but which is locked in closed position by the introduction of the bottle

DESK PAD—E. OLDENBUSCH, care of Kronheimer & Oldenbusch, 380 Butler St., Brooklyn N Y The present invention relates to desk pads and more particularly to a corner plate for desk pads so constructed that in addition to performing its usual functions of confining a corner of a sheet of blotting paper it may also be used as a receptacle for small cards and other articles.

BURIAL VAULT—J BERMEL, 2210 Metropolitan Ave Middle Village L. I N Y The object of the present invention which relates to a previous patent No. 983,804 is to provide an improved vault arranged to accommodate one or a plurality of bodies and to protect the latter from vermin by providing hermetically sealed catacombs or compartments, one for each body these compartments being practically airtight and waterproof

COMBINED TABLE AND MAP RACK—K W SCHWARZ, 615 Center St. Little Rock, Ark The invention consists of a table with a box supported under the table top. In the box is a rotating cylindrical casing provided with a number of rollers for accommodating any desired number of maps. The maps may be drawn out of the cylinder, and through a slot in the table top, and spread out upon the table

BLOTTER HOLDER.—J L. HAYES care of Lee Hayes, P O Box 1375 Butte Mont The holder is made of resilient material with flanges at its ends for holding the blotter against the body of the holder and with the central portion of the body formed in a spring loop which serves as a handle and also as means for holding the flanges yieldingly in position

TRUSS—J T HAILE, Utopia, Tex The aim is to provide a truss, arranged to permit in placing the pad into any desired position securely holding it therein to prevent irritation of the body and to render the pad pliable and at the same time maintain the uniform pressure on the afflicted part

STREET SIGN—J STRACHAN 384 36th St. Brooklyn, N Y The principal object here is to provide a sign having means thereon whereby it may be secured in position on the sidewalk, the construction and arrangement being such that portions thereof are protected from injury by the wheels of passing vehicles.

NAIL STRIPPER—C F SMITH 412 E. 16th St Los Angeles, Cal In this device different sized nails may be inserted, the nails automatically alining themselves so that they may be withdrawn heads up. This is obtained by positioning within a suitable casing an inclined hopper from which the nails are fed in grooved tracks, from which they may be readily withdrawn in assembled order

Hardware and Tools.

HANDTOOL.—B MORGAN Newport, R. I Mr Morgan's improved handtool may be used as a clamp or as a spreader and stretcher for coil springs or as a valve lifter. It consists of a screw rod bearing two jaws, one fixed and the other movable upon the rod, a lever and ratchet mechanism being provided for this purpose

TELESCOPING POCKET RULE.—F C GREATHEAD, 1835 Weton St. (rear) Denver Colo. This telescoping pocket rule is of simple construction and arranged to hold compactly and yet may be extended or folded with the use of but one hand. It is made of a number of telescoping sections provided with enlarged rear portions having sliding engagement with the following sections and having a contracted front end for the enlarged rear end of a preceding section to abut against.

PIPE [illegible] Beacon St., Boston, Mass. [illegible]

INQUIRY COLUMN

Inquiry No. 9287 Wanted to buy a machine which will reduce cobs to meal—not a machine for shredding the cobs, but a machine that will pulverize them.

Inquiry No. 9288. Wanted the names and addresses of concerns that can cast steel balls with pure tin one-sixteenth of an inch thick.

Inquiry No. 9289 Wanted substance melting at 225° and hardening when cold without imparting any flavor to tobacco smoke and without emitting any oily or fatty vapor

Inquiry No. 9290 Wanted name and address of a manufacturer of a patented device which is suitable for making up pay envelopes, namely, to fold up bills and insert them with silver coins in a pay envelope of the usual size.

Inquiry No. [illegible] Want to buy machinery for [illegible]

Inquiry No. [illegible] Wanted a [illegible]

Inquiry No. 9294. Wanted the names and addresses of manufacturers of waterproof cloth, also samples of such cloth.

Inquiry No. [illegible] Wanted to buy [illegible] [illegible]

is an improvement in the type comprising a fixed jaw and a moveable or sliding jaw the latter being formed integral with the shank which slides in the handle and is provided with a screw thread to which a portion of the handle constructed as a nut is applied for the purpose of adjusting the movable jaw The fixed jaw has an inwardly inclined face and the adjustable jaw is formed with a V shaped toothed biting surface.

Heating and Lighting.

GAS GENERATOR.—M Davidson 46 Rue de Chateaudun, Paris, France. In the present patent the invention has reference to improvements in gas generators and has for its object the provision of a gas generator the vat of which is so suspended as to keep the approaches of the hearth completely clear

FLUE CLEANER.—G C. French, Eldora, Iowa. This invention refers to cleaners for freeing the flues of boilers and other apparatus from accumulations of soot, scale and the like and has reference more particularly to a flue cleaner which comprises an elongated flexible body having an adjustable scraper mounted thereon

PORTABLE CREMATING CLOSET AND GARBAGE DESTRUCTOR.—N Frost care of Am Foundry & Furnace Co., Bloomington Ill This apparatus is more especially designed for use in camps and other places having no sewers, and arranged to incinerate excreta and to evaporate urine etc and to destroy garbage or other loose material and to utilize the loose material as fuel for incinerating purposes.

OIL BURNER.—T J Langston Johnston, S C. The principal object of the present invention is to provide a device by means of which oil such as kerosene may be vaporized and burned in a gaseous state A further object of the invention is to provide a simple form of burner to be used in cooking and heating stoves, which is made up of pipes, elbows, T's, etc, of standard sizes and quality

Household Utilities.

DUMB WAITER GUIDE.—W F King 46 Stuyvesant Place New Brighton, N Y, N Y This guide is made entirely of metal so as to comply with municipal ordinances relative to the exclusion of combustible materials from elevator or dumb waiter shafts Means provide for anchoring the guides to the wall or walls whereby the guides may be easily adjusted to make them adapted for different constructions of elevator cars, and easier of installation than those now in common use

Machines and Mechanical Devices.

FIRST COMBING MACHINE OF CARDING ENGINES.—T F Poiret, 40 Rue St. Denis, Paris, France. This invention relates to improvements in automatic unraveling conveyers for a wool-carding engine in which the wool to be carded, being placed in a trough is seized by a toothed drum rotating in said trough and afterward evened upon the drum by a saw toothed comb having an oscillating motion tangent to the drum and acting alternately

FRUIT DRIER.—L. R. Skinner, Dunedin Fla This particular machine is adapted for drying oranges, grapefruit and the like subsequent to the operation of washing them. In the machine small streams of air are forced directly upon the fruit which is rotated so as to bring all parts into direct contact with the moving streams of air

BENDING MACHINE.—F T Root and G A Fenton care of Defiance Machine Works, Defiance Ohio. The present invention is an improvement on patent No. 603,026. Its object is to provide an improved wood bending machine arranged to insure positive movement on the bending arms to cause the timber to hug the form snugly and thus produce accurate bending of the timber

TAPPING MACHINE.—M. J Ford 125 10th St Scranton Pa The machine provides a means for quickly forcing a tap into a hole and as quickly unscrewing it. It consists of a casing provided with a suitable handle, in which is a step-down gearing connecting a motor with the handle that receives the tapper member in which the tap is mounted. The motor is preferably of the pneumatic type

MILL.—I C. Landes and M. C. Landes care of Landes Mill Works, Yerkes, Pa. The purpose here is to provide a mill in which the material entering the mill is caught by an auger having openings, the material being caught by the blade on the auger, and being forced by the auger into a recess formed by a disk and the casing of the mill, where the rotation of the material is retarded by radial stops, while the blades of the auger act on the middlings to break it up, so that it may be bolted through bolting cloth

OPERATING MECHANISM FOR FLUSHING DEVICES.—O Kreter and G B. Kreter, care of Kreter & Son, 616½ Market St., San Antonio, Texas. This invention relates more particularly to the combination of an actuating member adapted to be operatively associated with a flushing device and with water closets and the like, an operating member tending to maintain a normal position and adapted to be actuated by a closet seat, and a dog operable by the seat and adapted to engage said operating member during a predetermined [illegible]

PNEUMATIC ACTION.—A Alter 500 E. 83rd St. Manhattan, N Y N Y The invention pertains to piano players, player pianos and like instruments having pneumatics, and the object is to provide pneumatic action which is exceedingly sensitive and insures a quick deflating and refilling of the pneumatic and thus allows sounding of the same note in quick succession

GATE CONTROLLING MEANS.—A F Giles, 632 Brinker Ave Latrobe Pa This invention provides for automatically locking the gate when the cage has been brought to the proper position at a landing automatically holding the gate open so long as the cage remains in the predetermined position and for automatically releasing the gate and causing it to close when the cage is moved above or below the landing or other predetermined point

LOGGING JACK.—C D Moore Kirkland, Wash In this jack a rack bar is raised by means of a pivoted lever provided with a pawl adapted to engage a rotatable ratchet connected with the said rack bar through the medium of a pinion The objects of the invention are to simplify the construction, reduce the cost, lessen the friction, and increase power, speed and efficiency of the jack

CROWN PRINTING DEVICE.—W Jackson care of the Robert Graves Co 3rd Ave & 35th St Brooklyn, N Y In this invention use is made of an impression cylinder and a crown printing roll mounted to rotate in unison with the said cylinder and having periodical bodily movement toward and from the peripheral face of the impression cylinder to provide the wall paper passing round the said cylinder with crown imprints at desired intervals.

Railways and Their Accessories.

CAR DOOR.—S Walters 317 Morrison St Warren Pa The principal object here is to provide a door embodying means whereby the door when in closed position will lie flush with the side of the cars, means being provided for moving the door preparatory to opening it, suitable rails being provided whereby the door may be rolled to uncover the opening the door moving into a position remote from the side of the door

Pertaining to Vehicles.

BUGGY SHAFT SUPPORT.—R M Purdue, Franklin Ky An attachment for buggies is here provided which is adapted to support shafts or thills in raised position when the vehicle is not in use The device consists of a spring actuated hook fixed to the buggy front and adapted to engage with the cross bar on the shaft.

BRAKE MECHANISM FOR AUTOMOBILES.—R. S Pelton Monticello New York This invention provides separate and independent brakes for the rear driving wheels of the automobile so that either wheel may be locked when it is desired to prevent its slipping in the mud the propulsive effect of the motor being in such case applied to the other wheel resting on dry ground

SHOCK ABSORBER.—W H Ball, 272 W 139th St Manhattan N Y N Y This inventor provides means for checking the free operation of the carrying springs of a vehicle when acted upon by the irregularities of the road, provides for simplifying and economizing the construction and provides an absorber shaped to vary the operation in accordance with the degree of vibration

VEHICLE TIRE.—H L Beaver care of J S Schuster, 288 E 157th St., N Y, N Y This invention relates to vehicle tires such as shown in Letters Patent No 371 945 formerly filed by Mr Hittner The present invention provides a tire for wheels of automobiles and other vehicles and arranged to provide the desired cushioning effect, without use of inflatable tubes, to render the tire puncture-proof and to permit of quickly making repairs when necessary

Note.—Copies of any of these patents will be furnished by the Scientific American for ten cents each Please state the name of the patentee, title of the invention, and date of this paper

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor

We are prepared to render opinions as to validity or infringement of patents, or with regard to conflicts arising in trade-mark and unfair competition matters.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

The Evolution of Worlds

The Work of Sir George Howard Darwin

By John W. N. Sullivan

THE great conceptions of science have always possessed a more than scientific interest. The Copernican theory in astronomy important as it was from the purely scientific point of view, was of still greater importance as a powerful factor in freeing men's minds from that local and narrow view which considered our planet to be the center of the universe and all the starry hosts of heaven to be somewhat in the nature of pleasing ornaments. The Newtonian theory of gravitation also by showing that one great law reigned throughout the solar system gave a unity to nature of the greatest philosophical and religious significance. And in our own time the theory of evolution introduced as a hypothesis in the realm of biology has influenced our conceptions in nearly every branch of knowledge.

One of the most fascinating illustrations of the general principle of evolution is found in the history of the origin and growth of the members of our solar system. It is fitting that the son of the man who told us so much about the origin of species should be the man to tell us so much about the origin of worlds.

George Howard Darwin the second son of Charles Darwin was born at Down in 1845 and died at Cambridge on December 7th 1912. As a student he gained high mathematical honors at Cambridge that breeding place of great mathematicians, and became Plumian professor of astronomy in the University in 1883. His interests embraced economic and political science besides purely mathematical subjects and he was in fact called to the bar in 1874. Considerations of health however led him to return to Cambridge. His greatest achievements have grown out of his interest in the theory of the tides. Newton was the first to give anything like a scientific explanation of their occurrence and he gave a satisfactory account of the main features of the phenomena. The principles of further developments were laid down by Laplace and were afterward applied in a magnificent manner by Kelvin. It was at this point that George Darwin took up the subject and the patience and tenacity he showed in performing vast and intricate numerical computations reminds one singularly of the same qualities shown by his father in collecting data for his theory of biological evolution. The main lines of tidal theory are well known. Most people are aware of the fact that the attraction of the moon and of the sun causes a kind of hump in the sea which travels round the earth owing to its rotation. The moon is the more powerful agent and the two humps it produces (one on the side of the earth nearest the moon and the other on the opposite side) travel round the earth in about 24 hours 50 minutes whereas the humps caused by the sun travel round in 24 hours. When the lunar and solar tides coincide we have spring tides and when they act against one another we have neap tides. Such in brief is the main outline of the subject, but to pursue it into its details requires a vast amount of complicated mathematical analysis. But apart from the details of the actual tides experienced on our earth they have a significance of far greater interest than themselves. They throw light on the origin of some members of our solar system. The tides do work—sometimes useful work, as in scooping out convenient landing places for our great ships and sometimes useless work. But in any case the dissipation of energy is involved and as we know that energy cannot be created the question arises where does it come from? The earth possesses a large store of energy in virtue of its revolution and ultimately the energy daily expended by the tides must come from that. But the earth's store of energy, though great, is not infinite and it must follow that the earth's store is decreasing, in other words, that the earth is slowing down in its revolutions. Of course this slowing down is excessively minute nevertheless it exists and it follows that in ages long past the earth must have been rotating appreciably faster than at present. As we trace things back farther and farther we find the earth rotating faster and faster and so the length of the day becoming continually less. Is there any limit to this process? The answer is that there is a certain critical velocity at which the materials composing the earth would be unable to resist the strain consequent on the velocity of rotation and the earth would fly in pieces. This critical velocity has been calculated and it appears that the length of a day in those inconceivably distant ages would be between three and four hours.

The length of our present day of twenty four hours we have attributed to the action of the moon. The tides caused by the moon act as a kind of brake on the earth. But Newton's third law of motion teaches us that every action has its equal and opposite reaction. What has been the reaction of the earth on the moon? *The earth has driven the moon farther and farther away.* The principle of the conservation of the moment of momentum teaches us that the momentum lost in one part of the system must be gained in another and therefore as the earth slows down the orbit of the moon becomes larger. The length of the day is increasing, and so is the length of the month. In remote ages when the earth was rotating much faster than it is now the moon was much nearer than it is now. The relation between the velocity of rotation of the earth and the distance of the moon has been calculated and we reach the enormously interesting result that at the time when the earth was rotating with the critical velocity of between three and four hours the moon was at such a distance that it was just grazing the surface of our planet. This cannot be a mere coincidence. We are irresistibly impelled to the conclusion that we have reached the time of the birth of the moon. In that remote age the earth *did* fly in pieces. It broke up into two great lumps and one of those lumps was the moon. At that time the length of the day and the length of the month were equal. Since then the earth has been driving the moon away and the moon has been slowing down the earth. But the ratio of the month to the day has not been steadily increasing. It is true that it increased to a certain point but then it started to decrease. Long before the dawn of history perhaps before the appearance of men on this planet there were more days in the month than there are now. At the period of maximum there were twenty nine days in the month or in other words the earth completed twenty nine revolutions on its axis while the moon completed one revolution round the earth. Since then the ratio of the month to the day has become steadily less. This process will only cease when the tides cease to act as a brake. This can only be when the earth rotates in the same time as the moon so that once again the day will be as long as the month. So far as the earth moon system is concerned this condition will be dynamically stable. Having once been attained it will never alter. It has already been attained by the moon itself. It is well known that we only see one side of the moon which means that the moon rotates on its axis in the same time in which it rotates round the earth. The earth-caused tides on the moon have done their work. If in that far distant future any considerable part of the earth is still fluid, the solar tides may cause a still greater increase in the length of the day and it may be that instead of the day being equal to the month, finality will be reached with a day longer than the month. This is what seems to have happened with the planet Mars.

Mars is probably older than the earth, and it is considerably smaller, so that

tidal action should have already accomplished there what still lies in the distant future for our earth. Now one of the most astonishing things attending the discovery of the satellites of Mars in 1877 is the fact that the interior satellite Phobos revolves around Mars in 7 hours 40 minutes, while Mars revolves on its axis in 24 hours 37 minutes. There can be little doubt that this result is a direct consequence of the action of the solar tides on Mars, and is, as it were, an experimental verification of the mathematical predictions sketched above.

This necessarily brief and imperfect account of some of the most important work of the late George Darwin may serve to give the reader some idea of the magnitude of the problems which engrossed him and of the far reaching importance of the results to which his genius led him.

His results aroused the interest of many other mathematicians, particularly the late Henri Poincaré, and there is no fear but that the subject will continue to receive the attention its importance warrants, although the inspiration to conceive, the stubborn patience to grapple with all difficulties, and the magnificent ability to overcome them is hardly likely to be greater in his successors than it was in the great Englishman who has so lately vanished forever from among us.

A $100,000 Prize for a Gasoline Substitute

By Stanley Petman, M. E.

FOR years it has been prognosticated that the supply of gasoline eventually must prove inadequate to keep step with the demand. Lately, developments would seem to indicate that there has been more than a grain of truth and true prophecy in the forecast, for with the production of motor cars steadily increasing at a rate that in not a few circles is viewed as alarming, the best efforts of the oil producers apparently are unavailing to meet the requirements.

At least the price of fuel for automobiles steadily has soared—in a little more than one year it has gone up 88.8 per cent in America by leaps and bounds—and whether or not the true reason for the rise in price is good old "supply and demand," as so glibly is set forth by the oil barons themselves, the ultimate result is the same, i. e., the automobile owner must bear the burden.

That such conditions could not be allowed to endure long has been evident, for no man will stand idly by with folded hands when there is the ghost of a chance of ameliorating affairs. But the amelioration naturally will require the expenditure of much money and the devotion of much time to be effected. Within the past few weeks, the British Society of Motor Manufacturers and Traders has offered a prize of $100,000 for a fuel which may be used instead of petrol, as gasoline is styled abroad. For some time, foreign motorists have used benzol, which is a coal tar derivative, as a substitute, but realization of its value has resulted in its price being boosted almost to that of gasoline. Added to which it is procurable only in limited quantities as compared with the supply of gasoline.

All of which emphasizes very strongly the necessity for some sort of concerted action to relieve the situation, which rapidly is reaching the state where it is unbearable to motorists, who carry the heavy end of the load, and to every one else who uses internal combustion engines operating on the lighter distillates of petroleum.

At last, however, the International Association of Recognised Automobile Clubs, the membership of which is composed of representatives from the most influential automobile clubs throughout the world, has seen the light of necessity and has stepped into the breach by offering to finance the donation of a cash prize of $100,000 for the best all around fuel other than "petrol," or gasoline, which will satisfactorily take the place of the petroleum product.

The decision to offer the prize was made at the last meeting of the association,

which was held last month in Paris when it was arranged that each of the big clubs in the organization representing France Great Britain, America Germany Belgium Italy Sweden Denmark Austria Holland Hungary Russia Switzerland Roumania and Egypt, should subscribe its portion to a general fund which shall constitute the prize. A special organization committee already has been named to go ahead with the work. Baron de Kuylen de Nyvelt is chairman and makes his headquarters at the offices of the International Association of Recognized Automobile Clubs in Paris.

As regards the contest itself the restrictions are very simple. The fuel must be suitable for existing internal combustion engines. It must be less expensive of course. It must be readily procurable. It must be of such nature that it cannot be cornered by trusts national or international. That is all.

Prior to the formal announcement of the conditions in detail which are now in course of preparation in the hands of the committee and which in sum and substance will be as given above assurances will be obtained from the various governments that the new fuel will be untaxed or at least that it will be taxed only very moderately.

A Comparison Microscope

(Concluded from page 15)

highly advantageous to be able to compare directly under the microscope a specimen of the suspected article with a specimen of the same foodstuff of unquestioned purity.

In many other investigations in botany zoology mineralogy bacteriology and especially in medicine the comparison microscope would prove equally valuable.

An instrument of this character which can be adjusted to show two objects in the two halves of its field of view is illustrated in the accompanying photograph. It consists essentially of two microscope objectives optically connected with a single eye-piece by means of four total reflecting prisms two placed under the eye piece and one at the top of each objective tube.

The pinion ... serves for the rough and the micrometer screw *B* for the fine focusing of the microscope any difference in the thickness of the objects or their carriers being compensated by means of the screws *C C*.

The two prisms beneath the eye piece are mounted on a slider which can be moved to right or left by turning the pinion *D* so that the field of view can be occupied entirely by either of the microscopic preparations or divided equally between the two. The median position of the prisms is marked and maintained.

The instrument therefore is virtually equivalent to two microscopes of the ordinary type but it possesses the additional and important advantage that the two objects under observation can easily and instantly be brought into the same field of view for close comparison.

This comparison microscope which is protected by a German patent is mounted on a hinged stand so that it can be used in a vertical or inclined position and it can be fitted with every accessory of the most elaborate microscope.

The Current Supplement

IN the current issue No 1937 of our SUPPLEMENT W Rosenhain concludes his article on Alloys Suitable for Instrument Work. Dr J E Teeple writes on Wood Waste Utilization.—Some extensive river improvements on the Missouri in which concrete piles have been used are described in an illustrated article.—Jean Dawson reports on the campaign against flies which the city of Cleveland has been waging with much determination.—Messrs Ellis and Dray describe a system whereby oils can be used in the ordinary type of gas engine.—Prof Runge writes on the Significance of Spectroscopy for the Atomic Theory.—Prof. Foley describes a remarkably elegant method of photographing sound waves.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents subscriptions books etc This will greatly facilitate answering your questions as in many cases they have to be referred to experts. The full name and address should be given on every sheet No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request

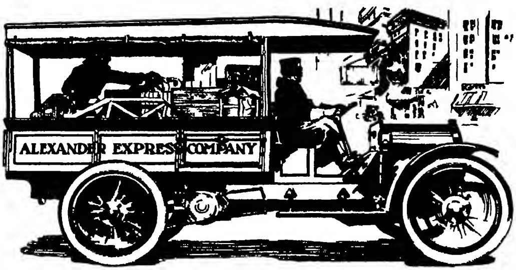
(12744) J A J H asks From time to time in houses I have seen weather glasses not of the mercury or aneroid classes In appearance these consist of a large-size test tube nearly filled with a pale yellow liquid with some white feathery substance floating in it Can you tell me on what principle these predict unsettled weather? Do you know of a receipt for making up the contents of the tube? In your opinion is this form of barometer (?) reliable? A The so-called weather glass, or storm glass is in no sense a barometer It contains alcohol in which camphor and other substances have been put a larger quantity than will remain in solution The glass is then sealed No effect of air pressure can reach the liquid within the glass There would seem to be no element of the weather excepting the temperature which can affect the liquid in the tube It is not possible that moisture should produce any change in the amount of camphor dissolved in the alcohol nor that this instrument should foretell the coming on of a storm A recipe given in the Scientific American Cyclopedia of Formulas price $5 is as follows 10 grammes of camphor 5 grammes of saltpeter 5 grammes of sal ammoniac 105 grammes of 90 per cent alcohol 45 grammes of water dissolved together

(12745) J F asks Can you tell me through your correspondence page which is the heavier—moisture or air? If this query is too general in character I can put it this way In discussing the reason for the excessive dryness of cigars kept in a case in which the moisture is supplied by a cylindrical device containing water which is suspended in the top of the case the point was raised that the moisture would reach the tobacco more effectively if the water was at the bottom as the moisture or vapor evolved by evaporation would rise rather than fall This led to a general discussion as to whether moisture or air as a general proposition is the heavier A Water vapor is about five eighths as heavy as air at the same temperature and pressure This however does not decide the question you propound because moisture will diffuse throughout any space in which it is, up or down whether the water is at the bottom or at the top All gases thus diffuse somewhat rapidly

(12746) C M M asks Will you kindly publish in the query column some explanation of the condition existing in many people myself in particular of what is commonly termed getting turned around or in other words, losing the cardinal points of the compass when traveling away from home I have in mind certain conditions in various cities under which it seems absolutely impossible to realize north as being in its proper place, even though I know it to be so A The fact is that every man is peculiar in certain points and to different degrees One man has an acute sense of direction so that he can tell the north and south direction in almost any place another is as you express it turned around very easily and cannot tell the direction in which he should go on coming out of a door upon a city street. It may be a dullness of sense perception and it may be that the man has not tried to educate his sense of direction It seems to be an individual peculiarity just as many other matters of sense and disposition are peculiar to an individual and constitute the individuality of the person

(12747) C F S asks I have been using an aluminium vessel partly filled with water in which a little baking soda has been placed for boiling silver ware in order to brighten and polish the silver ware. I had read the directions in a newspaper and tried the process with good results Would you kindly advise the chemical or physical principle by which the cleaning and polishing or brightening is done? Is it injurious to the silverware? A The process you describe for cleaning silver is mostly electrical or electrolytic the current between the silver and aluminium taking off an extremely thin layer of silver and leaving the ware clean Probably no more silver if as much is removed at each cleaning than would be removed by polishing with an abrasive silver polish.

(12748) J W G asks 1 A question in physics is under discussion. What is the lowest temperature that ice can register? I am informed that 29 1/5 deg Fahr is the lowest A. After water has frozen the ice is a solid and may be cooled to any degree below freezing just as any other stone may be. It cannot be heated above 32 deg. Fahr which is the freezing point of water and the melting point of ice 2. What is the reason that the heat is not lowered when ice is formed in a freezing mixture of say minus 200 deg Cent.? A. When water freezes it gives off heat, which tends to warm the surrounding air and cannot cool it as you seem to suppose. In a freezing mixture the ice is melted, and the heat necessary to melt the ice is taken out of the substance which is to be frozen, as in making ice cream. 3. Is ice a practical insulator at low temperature, and why? A In a sense ice might be called an insulator for heat, but the heat of the sun passes readily through it and may be felt on the other side of the ice. A piece of ice may be made into a lens and the heat of the sun focused by it so that it would burn the skin.



The First Aid for Better Business

The Willys ¾ Ton Utility Truck—$1250
(Chassis Only)

ALL over America there are thousands of concerns that could further develop their business by simply adding some modern equipment. Take one item alone—and a very costly one, too—the hauling of merchandise. One Willys Utility truck will enable you to extend your delivery operations 100—200—300, and in some cases, even 400%—depending, of course, upon your local conditions—*with no additional help.*

The very best work the very best single horse can do is eight to ten miles each way per day The Willys Utility truck can do 30 to 40 miles each way per day and then work all night if necessary Which figured from another angle means that one of these trucks can do five to six times as much practical delivery work as any six horses you own

This truck can accomplish more than any other of equal power and capacity and costs you considerably less

This is the most practical small truck ever built It is not a built over or revised pleasure car chassis—it is a practical truck built along practical truck lines by practical truck builders in one of the largest and foremost exclusive truck plants in America We build nothing but trucks and have been building them successfully for over ten years

Note the following practical truck specifications

The powerful 4 cylinder motor is controlled by our patented governor it cannot be driven over 18 miles an hour it has quick demountable solid tires 36 x3 front and 36 x3½ rear it has an unusually rugged pressed steel frame doubly reinforced at points where it will receive the greatest strains the wheel base is 120 inches

For further particulars see the nearest Gramm dealer or write us direct

The Scientific American Publications

Scientific American (established 1845)	per year	$3.00
Scientific American Supplement (established 1876)		5.00
American Homes and Gardens		3.00

The combined subscription rates and rates to foreign countries, including Canada, will be furnished upon application. Remit by postal or express money order, bank draft or check.

Munn & Co., Inc., 361 Broadway, New York

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement.

A Standard for Safe Railroad Travel

THAT the risks of railroad travel in the United States are beyond all reason is admitted. The question of the safety of the American railroad passenger is a relative one—to be determined by some accepted standard. For such a standard let us go back to the British Board of Trade's statistics of accidents in the United Kingdom for the year 1908, when out of one billion five hundred million passengers carried not one was killed. In that same year our Interstate Commerce Commission reported that out of less than a billion passengers carried, the number killed in train accidents was 105.

But we do not have to go outside of New York city for a standard of safe travel that exceeds even the British record, always bearing in mind the density of the traffic. The New York subway during the eight years of its operation has carried 1,664,510,822 passengers without a single fatality due to train accident. What makes the record so astonishing is the fact that about 70 per cent of these people were carried on express trains running at from 40 to 50 miles per hour and under the unprecedented headway (for the past few years) of 1 minute and 11 seconds. This feat, which in view of the high speed and short headway has never been approached, has been accomplished under shelter, it is true, and free from the hazards of the weather; but it sets a standard which is not impossible of accomplishment, surely, under the vastly greater headway of a trunk steam railway. The subway record is mainly due to excellent block signals and the automatic stop. Both of these should be made compulsory on steam roads.

We are well aware that the question of safety is largely one of discipline; but the subway officials assure us that the automatic stop conduces to discipline, for the reason that every operation of the stop constitutes a record against the man who passes a signal.

Comparative Cost of Direct and Single Phase Electrification of Steam Railroads

IN the absence of any definite figures as to the relative costs of the New York Central direct current and the New Haven single-phase installation, great value attaches to the report on the tenders which have been submitted by the leading electrical manufacturers of the world for the electrification of the extensive system of suburban railways of the city of Melbourne, Australia. The city railways enjoy a practical monopoly of suburban traffic, and although the service rendered by steam locomotives has always been excellent, the growth of traffic has been so great that the city has turned to electric traction as the only solution of the problem.

The present traffic on the roads affected is about ninety million passengers per year, and it is estimated that in 1917, after electrification, the total will have reached one hundred and fifty millions per year.

Before deciding on the system to be employed the Government and the Railway Commissioners decided to have complete alternative schemes prepared, one on the direct and the other on the alternating current system. Specifications were drawn up and tenders were invited, in response to which offers were received from the leading manufacturers of the world, who prepared complete proposals accompanied by stringent guarantees. Before inviting tenders, special pains were taken to see that the rival schemes were comparable and fair to the makers of the different systems. Since no serious criticism has been put forward by the exponents of either system, it is reasonable to assume that they were fair to all the parties concerned. The suburban lines comprise some one hundred and fifty miles, and the cost of converting these lines on the direct-current system was $11,750,000. To convert the same lines on the single-phase system would have cost $15,275,000. These figures, it should be explained, relate only to those items of capital expenditure which would be affected by the different systems. A comparison of the annual cost of the operation of the two systems gave the following results: Direct current, $1,270,870; single-phase, $1,523,705.

So that from this comparison of costs, based on the proposals of the leading manufacturers of the world for electrifying the same 150 miles of road, we find that the direct-current system shows an advantage in first cost of $3,525,000 and in the annual cost of operation of $252,835. It has been generally believed that although the direct-current system shows an advantage on suburban lines where the traffic is dense, it would be found that on longer lines with a relatively scant traffic the advantage would lie somewhat heavily with the single-phase system. In order to arrive at a just comparison, the engineer of the commissioners analyzed the relative cost of electrifying the Melbourne, Woodend and Bendigo line, which has a length of 100 miles. Even in this case it was found that the initial cost of conversion on the single-phase system would be greater by about $65,000, and that the annual cost of operation would be greater by about $8,100. The great importance of this comparison is realized when it is understood that the proposed conversion will cover altogether about three hundred miles of steam railroad tracks.

Under the direct current scheme, which is to be adopted, power will be supplied as three-phase alternating current at 25 cycles per second and a pressure of 20,000 volts. This will be transmitted, partly by underground cable, partly by overhead wires, to twelve sub-stations. There it will be transformed and converted to direct current at 1,500 volts. The trains will consist of from two to six cars operated on the multiple-unit system. The schedule speed for the suburban service, including stops, will be 21 miles per hour.

Shall We Have Compulsory Licenses?

THOSE who are responsible for the Oldfield bill seek to justify the introduction of compulsory licenses into the American patent system on the ground that England and Germany have adopted the principle with success. Representative Oldfield is haunted by the fear that meritorious inventions are suppressed.

Study the history of foreign patent legislation and you will find that the English and German working clauses were framed not for the purpose of preventing the suppression of inventions, but solely to protect manufacturers from foreign commercial invasion.

Thus, the English patent law is intended to give British manufacturers and the British workingmen an advantage over their more progressive German and American rivals, by declaring a patent forfeited if it has not been adequately worked within a stipulated period. Similarly the corresponding German laws, now all but abandoned, were intended to prevent foreigners from dominating German commerce.

If we may judge from the opinions expressed by British patent attorneys, England is awakening to the evil effect of her drastic patent laws. In a paper prepared for the Sixteenth Congress of the International Association for the protection of industrial property, held in London in June, 1912, Oliver Imray, Fellow of the Chartered Institute of Patent Agents, and Hugh Fletcher Moulton, Barrister-at-Law, had this to say with reference to the British Compulsory License Provision:

"The passing of Section 27 has certainly introduced an additional and very serious and complicated ground on which the validity of every patent can be attacked after four years, thus rendering it far less secure as a property, destroying to some effect the monopoly of fourteen years heretofore granted to a patentee, and deterring capitalists from financing the invention and so introducing the industry into this country. . . .

"The results obtained are infinitesimally small compared with the largest number of existing patents (100,000), even after deducting from this number those patents which may be considered of minor importance, and this, in itself, is an absolute proof of what a small call there was for this very serious and drastic alteration of the law, an alteration practically admitted by all countries from many years' actual experience to be a mistake. . . . For this very unimportant result, a slur on or an additional ground for questioning the validity of all the remaining patents stands out as a deterrent to the investment of capital for exploiting what may be very valuable inventions. . . . The effect of the passing of Section 27 of 1907, which we cannot help condemning as a retrograde step, has caused considerable agitation, antagonistic to British patentees in all countries of the world."

Between August 28th, 1908, and the end of June, 1912, eighty three demands were made for the revocation of patents, because the inventions which they covered were manufactured mainly in foreign countries. Of these eighty three demands no less than twenty were granted. On the other hand only one demand was made for the granting of a compulsory license and that demand was withdrawn by agreement between the parties.

The harshness of the British Act may be judged from a brief review of actually decided cases. Anyone can apply for an order, whether or not he has a real interest in developing British industries or not. It is irrelevant whether the applicant shows that the order will develop an existing industry or lead to the establishment of a new industry. Even though the sole purpose of the applicant is to import foreign made articles into the country free from the restraint of a British patent, the order must be granted. The lack of a demand in Great Britain for the article protected by the patent is not accepted as any excuse for failing to work it. If the article is made anywhere else in the world the patent owner must set about creating a demand for it in Great Britain. It will not suffice the patent owner to show that he has made genuine attempts to dispose of the patent, unless the Comptroller happens to agree that these efforts are all that a British business man should reasonably have made. The fact that a patent owner has done the best he could according to the standard of his own country or the country where the article originated is not enough. It will not suffice that the patent owner simply advertised that he desires to dispose of his patent, or that he sent around circulars stating that he wished to sell his patent, or intended to enter into a working arrangement to manufacture it in Great Britain. If the Comptroller finds that the advertisements, circulars, or other offers were framed vaguely and gave no intimation of the terms on which the patent owner was prepared to treat beyond the statement that such terms would be reasonable, the order must issue. Finally the Comptroller may decide that the unlucky patent owner, besides advertising and offering his patent to British manufacturers, ought also to have given demonstrations of the invention within Great Britain.

These actual British cases are of interest because some of them could easily arise if the Oldfield bill becomes a law.

Germany's experience has not been more encouraging. Indeed, the clause in the German patent law which required the working of patents has been practically abolished. Only in case the public interest (not the selfish interest of a private manufacturer, as the Oldfield bill would have it) is at stake will the Government interfere. Thus, the discovery of a new chemical compound which would curb an epidemic might be appropriated. This slight remnant of the old practice has been retained, not because of any unshakable belief in the virtue of revocation or of compulsory license, but because the German government feels the need of a weapon in negotiating patent treaties with countries that compel the working of patents. Such is the explanation of the German attitude given by A. duBois Reymond and Prof. Dr. Osterrieth, both distinguished authorities on German patent practice and both of whom have expressed their opinions in separate papers included in the recently issued report on the Patent Office submitted by the President's Commission on Economy and Efficiency. Both assure us that the popularity of the working clause has steadily diminished as the German people became convinced of its utter worthlessness and of the annoyance that it caused.

If the United States Government wishes to follow the German practice and reserve to itself in the public interest the right to appropriate certain inventions, there is no need of any such measure as that proposed by Representative Oldfield. Under the existing patent law the United States Government has the right to appropriate inventions upon the principle of eminent domain—a right which it has not hesitated to exercise. But the Oldfield proposal goes far beyond this feature of the German law. It seeks to establish over every kind of patents a species of eminent domain for the mere private, selfish purpose of whomsoever seeks to apply for a compulsory license.

All the testimony taken before the Congressional Committee, to whom the Oldfield bill was referred, conclusively establishes three points. First, that the existing patents laws of the United States are on the whole superior to the patent laws of Great Britain, Canada, Germany, France and any other foreign nation. Second, that from the point of view of the public, the inventor, the manufacturer, and the consumer, the provisions of the substitute Oldfield bill regarding compulsory licenses are worse than the corresponding provisions of the patent laws of Great Britain, Germany, France and other foreign nations. Third, that the experience of Great Britain, Germany, France and every other foreign nation that has tried anything resembling compulsory license, as proposed by the substitute Oldfield bill, has proved that, from the point of view of the public, the inventor, the manufacturer, and the consumer, compulsory license is a failure, and a distinct discouragement of invention.

Science

A Remarkable Photograph of a Meteor Trail is published in the *Bulletin* of the Astronomical Society of France, having been previously published in India, where the original was, on account of its unique character, awarded the first prize in a photographic competition held by the *Times of India Illustrated Weekly* It was taken by an English sergeant, A Hempstead at Mhow India. The meteor, which was very brilliant, was visible for about 2 seconds in its passage across the sky, but its trail persisted for 20 minutes. The photograph taken 1½ minutes after the passage of the meteor shows the trail as a very irregular sinuous line—the result of drifting in the wind

Long-range Weather Forecasting, so long discredited by scientific men, appears to be gaining respectability, little by little, with the progress of meteorology The last annual report of the Dutch East Indian meteorological service mentions the fact that forecasts of the strength and weather characteristics of the easterly monsoon are now issued at Batavia each April Official monsoon forecasts have been regularly made in British India for many years. In the United States Weather Bureau, Sunday forecasts for a week in advance have become an established institution Of course in all these cases the forecasts deal with only the broader features of the weather over wide areas.

Cataloguing American Doctoral Dissertations.—The Library of Congress has undertaken the important task of preparing an annual catalogue of the printed doctoral dissertations submitted at the various universities in the United States, exclusive of those submitted for professional degrees. This is a class of literature which librarians and bibliographers find particularly elusive, so that the new publication will fill a long-felt want Through the co-operation of the university librarians the Library of Congress hopes to acquire copies of all doctoral dissertations hereafter printed in this country, and to print catalogue cards for them. Eventually an attempt will be made to compile a list of the dissertations published before the beginning of the annual publication

Weather Reports from Arctic Canada —At the last meeting of the International Commission for Weather Telegraphy, Director Stupart, of the Canadian meteorological service, announced that the Canadian government would shortly be asked, through the Royal Society of Canada, to establish wireless stations at several far northern points, such as York Factory, Fort Chipewyan, Fort Simpson, and in Hudson s Strait, If this is done, arrangements will be made to have daily weather reports forwarded from these places – This would mean a very notable extension of the weather maps of Canada and the United States. Mr Stupart also reported that his service is now making a daily synchronous weather chart of the northern hemisphere, similar to that prepared in Washington, and that its value in forecasting has exceeded his most sanguine expectations.

Temperatures in the Antarctic —Some of the meteorological results of Amundsen's antarctic expedition are discussed by Dr Hann in the *Meteorologische Zeitschrift* Continuous observations were made at Framheim during the ten months, April, 1911, to January, 1912, inclusive From these, by comparison with previous records in the antarctic, values for February and March can be computed On this basis the mean temperature of the station for a year is found to have been −25.2 deg Cent. (−13.4 deg Fahr), which is the lowest yearly temperature heretofore observed at any place on the globe. The lowest individual temperature observed was −58.5 deg Cent. (−73.3 deg Fahr) Much lower temperatures than this have been observed in the "cold pole" of Siberia.

The Remarkable Haziness of the Atmosphere that began in June, 1912, and persisted at least well into the autumn, continues to be the subject of numerous reports from widely scattered points in the northern hemisphere Dr A. de Quervain, the leader of the Swiss expedition that crossed Greenland last summer, states that blue skies prevailed on the west coast early in June, before the party started During the crossing, however, June 10th to August 1st, the members of the expedition were struck by the gray, leaden appearance of the sky, in the absence of clouds, and even when the explorers were traveling at altitudes above 8,000 feet. The Eskimo of the east coast were terrified at this unwonted phenomenon, which they believed to be an omen that the following year would have no summer A report from Zurich states that the haze ceased to be noticeable at the Swiss observatories about October 11th. Dr Maurer, president of the International Solar Commission, has sent a circular to the principal meteorological institutions of the world requesting a careful examination of the tracings made by sunshine-recorders during the period in question, as a means of ascertaining the intensity and distribution of the phenomenon The coincidence of the beginning of the haze with the eruption of Katmai volcano, in Alaska, seems to leave little doubt as to the cause of the phenomenon.

Automobile

Heaviest Military Motor Truck.—The heaviest motor vehicle which has fulfilled all the regulations of the French War Department in connection with the subsidy arrangements, is the Avant-train Latil, which ogether with the trailer has a carrying capacity of 20 tons

Automobile Brakes that Operate a Signal —Charles F Marston of Great Neck, N Y, in a patent, No 1,-049,749, provides a signal device which is so connected with the brake mechanism that the signal is operated when the brake mechanism is manipulated to set the brakes, so that an automobile approaching another from the rear will be warned when the automobile in advance applies its brakes to reduce its speed or stop, thus preventing rear end collisions

Germany Has 825 Subsidized Road Trains. According to figures which have just been issued by the German government 120 motor "road trains has been subsidized for the year 1913 by the kingdom of Prussia, and 15 by Bavaria. This number added to the 690 which were under the control of the government in 1912, there are now 825 of these motor vehicles at the disposal of the German military authorities in case of war

Next Paris Salon in October —In view of the fact that heretofore the Olympia Automobile Show at London has been held a few weeks before the Paris salon, the importance of the latter has diminished to such a degree as to make the French exhibit a mere "appendix" to the British show To counteract this impression and to recapture for France its former high place in the automobile field it has been decided to hold the next Paris automobile exposition in October instead of November, so as to antedate the Olympia exhibit

Accident Statistics for Motor-car-miles --Someone with a predilection for statistics has figured out that in Great Britain alone about 1,600 000 000 miles are covered annually by all sorts of vehicles including motor cars During the past year 750 persons were killed by vehicle traffic, that is to say, one person for every 2,133,333 miles. Motor vehicles to the number of 50,000 covered approximately 300 000 000 miles and killed 200 people, or one person for every 1,500 000 miles

An Automobile for Fording Rivers —In order to meet with the rigid requirements of some of the British colonies in respect to motor cars which can be taken anywhere and everywhere, an English manufacturer has brought out a model which can be driven for miles through water four and even five feet deep All electric conduits magneto and batteries are protected by special insulations and extra lengths of pipe are attached to the exhaust pipe and to the intake manifold When a car of this type is driven through five feet of water only the top of the radiator and the seats show above the surface

A Daimler Lubricating System —Patent No 1,050,-108 to the firm of Daimler Motorengesellschaft of Stuttgart Germany, as assignee of Paul Daimler and Albert Hess of Cannstadt, Germany, shows a lubricating system which has a number of pumps for supplying lubricant to a number of corresponding parts to be lubricated, the pump cylinders being connected in series and to the parts to be lubricated with each cylinder having an oil inlet port and a piston reciprocated in each cylinder and over-running the inlet ports, so that each piston will operate to supply oil to the next succeeding cylinder on the compression stroke of such piston

Improvements in Carbureters.—It is a pretty well acknowledged fact that the action of many of the carbureters at present on the market is not all it might be from the point of efficiency and flexibility In this respect it is interesting to note that a number of car manufacturers have obtained a material increase in efficiency by the simple expedient of fitting an auxiliary air valve controlled by the operator To the person who takes an active interest in his car and its running the increase in efficiency and flexibility which in many instances can be obtained with the aid of a manually controlled air port, will more than offset the necessity for attention to its proper setting according to the demands of the motor

New Use for Postal Automobiles.—The Bavarian government has found a new use for the many automobiles employed by the Post Office Department by means of which the danger of great conflagrations in the rural districts is minimized If a big fire breaks out in any of the villages farther than ten miles from a city, the fire engines of the nearest city are attached to the postal automobiles and hauled at high speed to the point of danger As only the larger German cities have motor fire departments, the assistance of the postal motor cars is invaluable to the surrounding villages The first practical test of the plan was made last month in Bamberg The village Walsdorf asked the city for help and a small fire engine was fastened to the rear axle of the automobile, the run was made in 34 minutes, and the assistance rendered by this engine was of great value in extinguishing the fire.

Aeronautics

A Proposed Aviation Field at College Park, Maryland.—On January 14th Mr Gallinger introduced in the Senate of the United States a bill to authorize the Secretary of War to acquire the land now leased to the United States for aviation purposes at College Park Maryland, for aviation maneuvers and other military purposes. The sum of $400,000 is asked to carry out the provisions of the bill

An Alexander Graham Bell Flying Machine Patent.—In patent No 1 050 601, Dr Bell, instead of making the supporting surfaces of a flying machine flexible at their lateral marginal portions and flexing or warping those portions to preserve or restore the balance of the machine makes such supporting surfaces rigid and non-flexible and employs a vertical balancing rudder which, when the machine is in normal horizontal position, lies approximately in the medial vertical fore and aft plane of the machine The rudder is mounted on an upright axis, and when the balance of the machine is disturbed, the rudder is by suitable means turned about its axis to incline it to that side of the axis toward the lower side of the machine, the resistance offered by the air as the machine moves rapidly forward, operating to again restore the balance of the machine when the rudder is returned to its normal position The axis of the rudder is preferably located approximately at the center of pressure of the air acting to support the machine For operating the balancing rudder, an arm projects from its upright shaft and has a fork which embraces the body of the aviator who, when the balance of the machine is disturbed, naturally inclines his body toward the upper or higher side, thus turning the rudder to the lower side of the machine for the purpose before described

Recommendations of the Chief Signal Officer of the United States Army —In his annual report to the Secretary of War Brig -Gen James Allen, Chief Signal Officer of the Army invites attention to the recommendation made in previous reports concerning the urgent need of legislation to increase the efficiency of the Signal Corps of the Army During the past few years the great development in radio-telegraphy, aviation, and in the organization of field signal companies has so greatly increased the duties devolving on the Signal Corps that the present authorized personnel is inadequate to perform the present work of the Corps He asks an appropriation of $3,-000 000 to be distributed as follows One million dollars for increasing the present equipment of aeroplanes, hydro-aeroplanes and other aircraft for the purpose of warfare and national defense, six hundred thousand dollars to be spent for one hundred aeroplanes two hundred thousand dollars to be spent for maintenance, including service, spare parts, gasoline oil etc , two hundred thousand dollars to be spent for auxiliaries, including hangars, tractors, motor-trucks etc , and one million dollars to be spent for the establishment of training schools known as centers of aviation, on the Atlantic, Pacific and Gulf coasts, on the Great Lakes and some central interior point and as many auxiliary centers as it may be possible to organize with a view to having a school of instruction in each State for the purpose of training officers of the regular army and organized militia as aviators

Curtiss Awarded Collier Trophy for 1912 and 1913.—Glenn H Curtiss flying motor boat, the last word in aviation, and the creation which is said to have made aviation a safer pastime than either automobiling or boating has won him the distinction for the second time, of receiving the Collier Trophy awarded annually for the greatest contribution to the advance of aviation, which shall have been developed and demonstrated during the preceding year The SCIENTIFIC AMERICAN Trophy was won by him in 1908 when at Hammondsport, N Y, July 4th he made the first public flight in America of more than one kilometer He actually flew a distance in excess of a mile in the old 'June Bug' In 1909 almost exactly one year later, Curtiss won the SCIENTIFIC AMERICAN Trophy for the second time at Hempstead Plains, he flew 24 7 miles or nineteen circuits of a circular course His famous flight from Albany to New York the longest flight of the year, won him the trophy in 1910 for the third consecutive time making him its holder in perpetuity In 1911 the new trophy, to be awarded for the most signal advance in aviation each year was offered by Robert J Collier then president of the Aero Club of America It was awarded to Curtiss that year for the invention and demonstration of the single pontoon hydro-aeroplane, the first machine to successfully rise from and alight on the water There is no record of a single serious accident to the operator of a hydro-aeroplane in America, though one machine and its operators were lost at sea in attempting to fly in a home-built hydro a distance of upward of 400 miles, from San Pedro to San Francisco, starting in a fog following a three days' storm The hydro-aeroplane perfected by Curtiss has been adopted by almost every navy of the world's powers.

Motoring on Ice

IF by putting skates on his feet a man can outstrip a horse, if by putting runners on a sailboat it can be made to race an express train why should not an automobile if mounted on runners develop a speed that would satisfy the cravings of the most voracious of speed maniacs? The logic is not perfect. Nevertheless an automobile has actually been mounted on runners and has attained remarkably high speeds. The experiment we refer to was made by Mr. Fred Waters of Red Bank, New Jersey. He stripped his car of all superfluous weight and mounted the chassis upon two pairs of runners. The rear wheels were left upon their axles, but the tires were removed and in their place toothed tires were used. The rear runners took most of the weight of the wheels, merely permitting the teeth to dig into the ice and snow and propel the machine. With this novel craft Mr. Waters had great sport travelling over the broad stretches of the Shrewsbury River.

He was not long without rival however. Mr. Phillips Green, also of Red Bank, came out with a peculiar craft built after the fashion of an iceboat, but provided with a motor in place of a sail. The motor was equipped with an aeroplane propeller. A crude-looking propeller it was too and it was driven by a 12 horse-power 2-cylinder motor. The automobile iceboat, on the other hand, was equipped with a 10 horse-power air-cooled motor. A race was arranged between the two sleds and the air-driven craft easily showed its superiority over the automobile. One of our illustrations shows the two machines just after the race. However, the automobile was more powerful when it came to travelling through snow and it was used to drive a snow plow to clear the ice, as pictured in one of the photographs.

One of the speediest of motor iceboats is the "Go-devil," built for Dr. L. Neumann after the design of C. H. Davis. It is fitted with a 40 horse-power, four-cylinder two-cycle motor, water-cooled, and an aeroplane propeller designed to drive the machine at 120 miles per hour. The propeller is placed in front of this boat and the steering rudder at the rear. When this machine was tried out last year at Irondequoit Bay, Lake Ontario, it developed such speed as to astonish the spectators. A reporter who was present was positive that the machine had made 140 miles per hour on the seven-mile stretch of good ice, and this story appeared in the New York daily papers. As a matter of fact the machine was not travelling at its highest speed, but was partly throttled down. The operator of the machine conservatively estimated the speed at about seventy miles an hour with the wind at his back, and he did not feel inclined to let the machine travel any faster on her trial trip at least. Unfortunately, the good ice did not last long and the next trial had to be made on snow-covered sheet. The snow was five inches deep. But even with this heavy handicap a speed of 40 miles per hour was easily obtained. The accompanying photograph of the "Go-devil" plowing through the snow at this speed shows how much of its energy was wasted in throwing the snow rather than propelling the machine forward.

Motor iceboating is in its infancy, but it is one of the most fascinating and exhilarating of winter sports, and its development in the past few years offers alluring promises for the future.

Astronomical "Bulls"

THE *Bulletin* of the Astronomical Society of France, otherwise known as *L'Astronomie*, has for some time been publishing from month to month, delightful specimens of popular ignorance concerning the elementary facts of astronomy, some of which have already been mentioned in our columns. The following are recent additions to the collection. An astronomer happened to remark that he had taken some photographs of the moon through his telescope, whereupon he was asked whether he took them by flashlight. A member of the French Academy, M. Rene Bazin, in his novel "Les Noellet," the scene of which is laid in Vendee, makes a peasant look up his cottage chimney one summer night, and see, in the zenith, the belt of Orion.

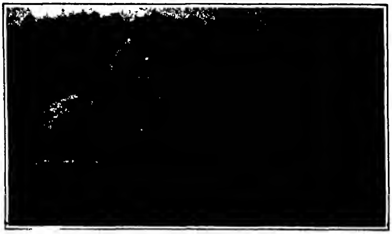
The Waterwheels of Hama

HAMA, in northern Syria, is justly famous for its huge waterwheels. The city lies some 110 miles northeast of Damascus on the banks of the river Orontes. It is undoubtedly a very ancient town, and is referred to in the Bible as Hamath the Great.

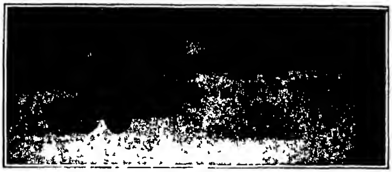
The river flows through the city in the form of an S, and upon its banks are four huge waterwheels, each bearing a name of its own. They are used for pumping up the water of the Orontes for irrigation purposes, and also for supplying the town.

The wheels are driven by the flow of the river on what is known as the undershot principle, that is to say, the wheel is moved by water passing beneath it.

Automobile sleigh and motor iceboat just after a race which the latter won.



Twelve horse power propeller-driven iceboat



Automobile sleigh clearing the ice with a snow-plow

The "Go-devil" plowing through five inches of snow

The largest wheel has a diameter of about 70 feet, and the Syrians declare it is the largest in existence. Like the others, it is built of wood, a dark mahogany. The axle is of iron. The creaking of the wheels is incessant day and night. They never stop. In winter and during early spring the flow of the stream is partially blocked to reduce the rapidity of the revolutions, but on no account are the wheels actually stopped.

Placed upon the banks of the stream amid the trees and gardens for which Hama is justly proud, the wheels present a decidedly picturesque effect. They are the favorite rendezvous of the boys of the town. For a few cents some of the more daring will climb up the spokes of the moving wheel to the summit and then jump into the stream below him.

Fortunes in Foxes

THE phenomenal expansion of the black fox industry in the province of Prince Edward Island, Canada, has been made the subject of an elaborate report by the American consul at Charlottetown. That province is, it appears, the greatest center for fox farming in the world, thanks to the possession of a climate and soil that ensure an ideal weight, texture, and color to the skins. More than 80 per cent of all the captive foxes in Canada are kept on Prince Edward Island.

Black foxes (which include the silver foxes) furnish a skin which is not only extremely valuable, but is in such constant demand that its value has become almost as fully standardized as that of the diamond among precious stones, and does not necessarily fluctuate with the supply. These skins frequently fetch from $1,500 to $3,000 on the London market, the record price up-to-date being somewhere between $3,800 to $3,900. Aside from the industry in skins there has grown up an immense business in live animals for breeding purposes. It is stated that during the past summer $10,000 a pair was not an unusual price, as compared with $4,000 a pair for animals of the same quality in 1910. Prices of $12,000 to $15,000 a pair are paid for animals that have shown unusual fertility, and it is rumored that a 2-year-old pair recently sold for $30,000. One of the pioneer ranchmen claims to have refused an offer of $500,000 for his establishment, coupled with a salary offer for his own services to run it. Fourteen companies for fox ranching have been incorporated in the island, and capital from the United States is beginning to be invested in these concerns. There are now about 50 large ranches stocked with pure-bred animals, while the number of places where from one to four or five pairs of some variety of foxes are kept is probably more than 300.

All the foxes on Prince Edward Island are now in captivity, the last wild fox having been killed early in 1911. It is claimed that the valuable strains have been improved in domestication. The animals are kept in pens or paddocks about 30 by 40 feet, surrounded by a large outer enclosure sometimes covering an acre or more. The fences are of 16 or 14 gage "fox wire," which is now specially woven for the industry. They are 9 or 10 feet high, with an overhung wire shelf extending inward, and are sunk 2 or 3 feet in the ground. The kennels or fox houses are inside each paddock, or immediately outside, but opening into it. The mouth of the kennel is a crooked tube or spout, often built to imitate the entrance to a natural burrow.

The diet of the animals is extremely varied, including meat, fish, fowl, small game, mice, and insects, beside various prepared foods, such as hardtack or sea biscuit dipped in milk and patent dog biscuits. Overfeeding must be avoided, especially at the breeding season, but a full diet for a few weeks before the pelt is taken is said to make the pelt more glossy, and is a common practice. Each animal costs from $10 to $15 per annum to feed.

The foxes often breed when they are but 8 months old. Each vixen, or female, will breed 8 or 10 times in the course of a lifetime, and a litter contains from 2 to 7 or 8 pups, the usual number being about 4. During the mating season the animals are exceedingly wild and shy, and, in fact, at all seasons, the fox is a very sensitive and high-strung animal, so that a great deal of experience is needed for its successful handling.

The recent rapid development of this industry has raised a number of difficult problems, which are gradually being solved. There is at present considerable agitation on behalf of some kind of registration of pure-bred island foxes, looking toward the formation of an association of breeders for the purpose of establishing a species of "herd book," in which to record pedigrees of valuable animals. It is expected that ultimately this task may be undertaken by the Live Stock Branch of the Dominion Department of Agriculture.

Our Latest Battleship "Pennsylvania"

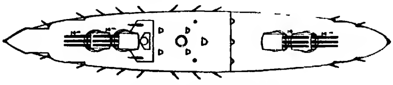
The Largest, Most Powerful and Best Protected Battleship in Any Navy

IT is the policy of our Navy Department to build its new battleships in divisions of five and to make these ships in every respect identical. It is part of this policy to send each of the ships of a division in turn to a navy yard for overhaul and general refitting, leaving the fleet in commission made up of so many divisions of four ships each. The Department asks annually for a sufficient appropriation to enable it, among other things, to build so many ships of a certain type. Usually, Congress appropriates the money more or less, leaving the question of design to the discretion of the Department, where it properly belongs. Occasionally, however, Congress has gone out of its way and specified what size or type of ship it desires. This is always disastrous, for it interferes with the Department's regular programme of construction and arbitrarily introduces into the fleet a ship or ships, which, because of differences in size, speed, turning circle, or arcs of training, cannot maneuver effectively with the ships of the divisions to which they are allotted. The "Idaho" and "Mississippi" are a case in point. They are small "Connecticuts," of 3,000 tons less displacement, a couple of knots less speed, smaller radius of action and other differences which greatly mar their usefulness.

When Congress appropriated last year the sum necessary for the construction of one unusually large battleship—some 1,500 tons larger than any existing ship in our fleet—the Department was confronted with the old problem, and had to determine whether to make the "Pennsylvania" come into the class of the "Nevada" and "Oklahoma," authorized the year before, or to constitute her the first of a new type. The "Pennsylvania" is an enlarged "Nevada," and in outward appearance is so like that ship that to any but the experienced eye, she will look, when she is steaming in division, to be practically identical. She will be forty feet longer, of about two feet more beam and a little more draft. Two guns will be added to the armament, giving her the powerful battery of twelve 14-inch guns. Like the "Nevada" and "Oklahoma," she will have oil burning boilers of the water tube type and, probably, she will be turbine driven. Her armor will be somewhat heavier, and as the "Nevada" and her sister are admittedly the most powerfully protected ships as yet designed, the "Pennsylvania," because of her size, gun power, and efficient protection, will take rank as the most powerful dreadnought built, building, or authorized by any of the leading powers.

The principal dimensions of the ship are: Length over all, 625 feet, beam 97 feet, draft, 29 feet, and displacement on this draft, 31,000 tons. This last will be her trial displacement, and it represents the flotation of the "Pennsylvania" when she is carrying two thirds of the full supply of stores and fuel and a full supply of ammunition. Her full load displacement will be 32,500 tons.

The "Pennsylvania" will be no less than 3,500 tons larger than the "Nevada." A part of this weight will be consumed by the two additional 14-inch guns and the greater weight of the two three-gun over the two two-gun turrets which they replace. There will also be, of course, an increased weight of ammunition. A large part of the 1500 tons also will be consumed by the increased length of the ship and the greater weight of the frames, decks, beams and deck plating due to her increase of beam. Then there will be a very large consumption of weight due to the increased length of the side armor. There will be a slight thickening up of the armor plan over that of the "Nevada." Furthermore, the boiler and engine plant must be enlarged somewhat to drive the heavier ship, although the fining out of her lines, due to her greater length, will go far to offset the increased load. Finally, and very important, will be the larger fuel supply, with the considerable increase which it will give to the radius of action.



Deck plan of the "Pennsylvania."

The disposition of the turrets will be similar to that of the "Michigan," which, by the way, affords the most efficient distribution of the guns for securing a maximum of all-round fire. There will be two three-gun turrets above the forecastle deck, the after guns training above the roof of the forward turret, and there will be a similar pair of turrets aft. This will give an end-on fire, both forward and aft, of six 14-inch and a broadside fire of twelve 14-inch guns.

The three guns in each turret will be mounted in a common sleeve, so that they will be elevated together, and the three shells, if there is no variation in the powder, must fall absolutely together—a matter of great assistance to the spotter. There will thus be four gun pointers in place of twelve, and errors of range should be greatly diminished. The torpedo defense battery will consist of twenty-two 5-inch guns carried chiefly on the main deck about twenty-two feet above the water line. The armament will also include four submerged 21-inch torpedo tubes.

In a recent discussion of dreadnoughts before the Society of Italian Architects, a distinguished officer stated that the dreadnoughts of the United States Navy were better protected than those of any other navy. Unquestionably this is a fact, and it is our decided opinion that the policy of making the protection of the flotation of the ship and her main armament of paramount importance will stand us in very good stead when it comes, if it ever does, to the trial of a line-of battle engagement.

The hull of the "Pennsylvania" is most fully protected. The main belt is eighteen feet in depth and fourteen inches in thickness, it extends far below the waterline. At the foot of it, from the armor shelf springs a 2-inch protective deck, which slopes upwardly to about the level of the waterline. At the top of the armor belt is an upper protective deck. The main belt extends to near the ends of the ship, and its extremities are joined in transverse bulkheads of heavy armor. The barbettes are 14 inches in thickness. The sloping port plates of the turrets are no less than eighteen inches thick. The roof armor has been thickened to five inches.

To protect the base of the single smokestack and prevent the escape of poisonous furnace gases between decks, heavy armor is carried around the base.

The battery of torpedo defense guns is without any armor protection whatsoever. To place relatively thin armor on this battery is to make certain the bursting of armor piercing shells, which might otherwise pass entirely through the thin plating of the ship.

Because of the wider space available due to the absence of side bunkers, the boiler rooms are placed together under one large central smokestack.

No attempt will be made to utilize additional displacement of the ship for any great increase of the motive power and speed. The speed will be only a little greater than that of the "Nevada" and "Oklahoma," or say about 21 knots.

The "Pennsylvania," therefore, will be an enlarged and considerably more powerful "Nevada." Her guns will have the same arcs of training and she will be so designed that she can maneuver with the same turning circles, etc., as her smaller sister. If Congress appropriates this year for two more "Pennsylvanias," we shall have a division of ships which cannot be matched in any navy of the world.

The "Pennsylvania" embodies the combined experience and judgment of the sea-going officers and the naval constructors, and the Department is to be congratulated in having produced such a fine compromise of the many conflicting requirements of the modern warship.

This "super-dreadnought," 625 feet long, will carry twelve 14-inch guns behind 18 inches of armor in four 3-gun turrets. In gun power and armor protection she is the most powerful ship in any navy.

The latest U. S. battleship "Pennsylvania" of 31,000 tons.

Protection of Wooden Poles Carrying Electric Wires Against Decay

IN *L'Industria* M. Maier proposes to protect that part of the pole sunk in the ground by encircling the critical zone of the pole (surfaces of contact between air and ground) for a variable height from 16 to 40 inches, according to the humidity and nature of the soil, with a round sheet of iron having a diameter of from 8 to 16 inches larger than the pole, so as to leave between the outer surface of the pole and the inner surface of the sheet an empty space, which is to be filled with a melted product derived from the distillation of tar and which boils at about 300 deg. Fahr. This product penetrates and saturates the critical zone of the wood and after is solidified in a uniform and compact layer, retaining, however, the necessary elasticity to follow the vibrations of the pole, at the same time protecting it from water and insects. Poles which have been already attacked by rot, and should be exchanged, may give further use by excavating the ground around them, scraping off the decayed part, burning it superficially with coal oil or kerosene and using the above described method. If it is necessary to remove a pole so protected, all there is to be done is to excavate the ground at one side, heat the sheet of iron until the mass inside is melted and extract the pole.

The Card Trick

To the Editor of the SCIENTIFIC AMERICAN:

In reference to the article "Another Card Puzzle," which appeared in the October 5th, 1912, issue of the SCIENTIFIC AMERICAN, I would advise those interested that the trick, as I call it, can be done with any number of piles of cards from one to five inclusive, the latter number being the best, as there would be fewer cards left, and if the face cards are valued at ten each, three added to the number of cards left will give the total of the bottom cards on the five piles.

To make this trick seem more mysterious, ask the party counting to put two cards on each pile, then one on each, or two on the first and second piles, and so on in any manner that you wish, until the cards remaining have all been used. This is done to find out the number of cards without asking for them or without letting anyone know that you must have the number. I find that this adds immensely to the effect of the trick.

Required, a Machine for Shaping Granite Cubes

To the Editor of the SCIENTIFIC AMERICAN:

A pavement somewhat similar to that which has been in use in the streets of Liverpool for a number of years past has recently been laid in Fulton Street in this city. This pavement, which consists of small granite cubes some three or four inches across, accurately cut so as to admit of laying with close joints, seems to be better adapted than any other to meet the requirements of heavy street traffic, and at the same time affords a good footing for animals. The chief obstacle to its extensive use lies in the fact that the cost is considerably greater than most other forms of pavement.

It has occurred to me that these granite cubes could be produced at a lesser cost if labor-saving machinery were employed in shaping them. Would you kindly call this requirement to the attention of inventors throughout the country, in the hope that they may be able to solve the difficulty? HENRY BRUOR,

Chairman Committee on Improved Pavement.

New York, N. Y.

[If the cubes are shaped by hand, their relatively high cost is readily understood. It should not be difficult to devise suitable machines for doing this work.—EDITOR.]

Determining Differences in Longitude by Wireless

To the Editor of the SCIENTIFIC AMERICAN:

The paragraph in your issue of October 5th regarding the proposed use of wireless by the Belgian government for the exact determination of difference of longitude, induces me to remark that this device was successfully employed last summer by Canadian government vessels. The work was performed by the "Arctic" and "Minto" and consisted in the charting of the Button Islands at the entrance to Hudson Strait.

While one vessel remained at anchor, the other visited the various islands which compose the group. Each day (the weather permitting) observers from each vessel made careful short observations for local time and then, as soon as possible, these times were compared by wireless.

The distances involved ranged from thirty to fifty miles, and it was found that by pressing the key at intervals of a minute for four or five minutes an accuracy in transmission considerably greater than that of the observation itself could readily be attained.

The method proved satisfactory in every particular, and its rapid extension seems assured.

Berlin, Ontario. W. B. WIEGAND.

The Carob Bean Tree

To the Editor of the SCIENTIFIC AMERICAN:

Your interesting article on "The Carob Bean Tree" in the January 11th issue of your highly esteemed paper reminded me of my observations of this tree. It grows here in a wild state, both the bean-bearing and the male tree. The latter is used for posts of various kinds, is very durable and hard, also rapid growth. The female develops less rapidly and has thorns from eight inches long down to very small ones on the smaller branches. The beans or pods are flat and black and measure as long as sixteen inches and about one and one half inches wide, the honey lying in the thicker portion of the pod and the beans in the thin. I have seen them over eighty feet in height, and the lumbermen call them "black locust." I know of a row of the male locusts near here, about one quarter mile long, which were originally posts for a wire fence, and were allowed to grow into trees now about fifty feet high. I have also seen telephone posts made of this variety which developed into beautiful trees. They bloom in early spring, with great clusters of pendulous, creamy white and very fragrant blossoms, the foliage is also very graceful. Cold does not affect this tree here. The Louisiana orange is grown some four hundred miles south of us and does not stand our climate. This tree is very hard to kill by cutting down, as it will invariably put out not only suckers from its most abundant roots, but will also sprout from the stump. The soil here is rich and sandy below the surface, with a good layer of rich black topsoil, the lowest stratum is gravel of an exceptional quality. In my younger days we would bind the long hard thorns to a lance of bamboo cane and use them for snake spears, and with their many tough prongs they answered admirably for this purpose. Incidentally I have used a smaller thorn in place of a lost suspender button, the utility of which can be imagined. The male locust is also known here as "locust and wild-honey" tree. Negro children sometimes eat the honey portion, but it is never used as a food. Neither the male nor female trees are ever green here, and we are perfectly bare of trees now. I have seen these trees in Miami, Florida, in Arkansas, Tennessee, Texas, and Louisiana, besides my home State, Mississippi. It is interesting to know that there is more value attached to this tree than was supposed here.

I send you this little article for what you may wish to do with it. I have had the benefit and pleasure of being a subscriber to and reader of your valuable paper for twenty years, and I still look for its weekly advent with pleasant anticipation. F. F. BRSSAC.

Natchez, Miss.

Misuse and Failure of Metals and Alloys

To the Editor of the SCIENTIFIC AMERICAN:

In order to bring about a better understanding between the users and manufacturers of metals and alloys, I venture to request the favor of the insertion of this letter. I hope it may provoke discussion, and if possible help us to arrive at the truth.

Users including the non-expert public of metals and alloys in general do not sufficiently realize that many of their corroded metallic wares, for example copper pans and boilers, mysterious breakages of for instance chains, railway accessories, and sudden failures of condenser tubes and copper pipes, are due to two easily preventable causes described below.

In order to satisfy the demand for beauty of form or the modern craving for cheapness, many ingenious mechanical devices have been evolved by manufacturers' works staffs, which put upon the metallic articles, while being made, uneven strains, or introduce in antiquated furnacing appliances deleterious compounds, which tend to and in varying times finally render the articles useless in the hands of the purchasers or users. Often enough they are dangerous to human life and property. An attempt is made to remove these strains by annealing in unevenly heated furnaces.

Why this state of things?

One must reply, "general ignorance," perhaps "apathy"—the major causes of most human troubles.

A few manufacturers whose products are subject to constant physical tests are quite alive to the situation. It must also be conceded that manufacturers of ferrous and non-ferrous metals and alloys spare no pains to free them while in the molten state from deleterious substances. They employ expensive nostra known as deoxidizers—ingenious devices to prevent contact of the liquid metal with the air during the casting operations, all tending to produce soundness in the ingots or castings, i. e., to free them from blowholes and segregations.

No sooner is this desirable end attained than the metal or alloy is introduced into furnaces wherein hot gases containing free oxygen, sulphur, and other objectionable elements are allowed to impinge upon or envelop the metal. While hot, they are brought out of the furnace into the air and mechanically treated in an atmosphere containing oxygen. This operation is often repeated several times. In cases of cold working, the metal, with few exceptions, is annealed between processes in furnaces to which the air has access. After this heat treatment they are withdrawn and allowed to cool, sometimes in approximately closed receptacles, oftener in the air. Not only is the surface of the metal oxidized or tarnished, but during the whole time of heating, and partly in cooling, solution of oxygen and other gases takes place, with formation of compounds in intergranular spaces, or in the body of the metal or alloy, which form centers or areas of corrosion when in use.

In the last year or two exact investigations and experience have proved beyond doubt that both the above defects in heat treatment are prolific causes of corrosion and the other breakdowns.

I therefore with all respect beg leave to submit that the time has arrived for all engineers and users of metals and alloys to insist and specify that, at least, two causes of failure of metals and alloys under the control of the makers shall be removed, namely: (a) Uneven heating appliances. (b) Antiquated heat treatment in chemically and physically active atmospheres.

Incidentally the public health will benefit, because all the appliances on the market capable of bringing about the above results are smokeless when in operation. The present unnecessary and wicked waste of one of our natural resources, viz., coal, will also be curtailed.

T. VAUGHAN HUGHES, A.R.S.M.

Birmingham, England.

Bursting of 13.5-inch and 14-inch Guns

To the Editor of the SCIENTIFIC AMERICAN:

In your number of December 14th last, when speaking of the bursting of an English 13.5-inch gun, which had taken place in Shoeburyness a few days previously, you alluded to the fierce controversy which had taken place a few years ago, respecting the question of the relative strength of the wire-wound guns and hooped guns. Starting from the justified assumption that the English gun which burst was wire-wound and of the most recent pattern, you recalled to mind that "the advocates of wire-wound construction claim, or did claim, before the recent improvements in hooped guns, that the wire-wound gun, because of the absolute inspection to which every part of it could be subjected, was proof against the kind of accident which recently happened at the proving ground."

From the wording of the article it results clearly that you had doubts as to whether the claims of the manufacturers of wire-wound guns were well founded, and I presume that these doubts will have been further strengthened by the bursting of a 14-inch wire-wrapped gun which took place at the Sandy Hook proving ground on December 9th. As appears from the *Army and Navy Journal* of December 14th, the gun, after having fired a first shot with reduced charge, burst at the second discharge with a normal charge of 320 pounds powder and a projectile of 1,660 pounds, producing a pressure of 42,000 pounds per square inch, while the contract strength of the gun called for a minimum of 55,000 pounds.

This is quite an extraordinary event, which, taken together with that which had taken place in England, where the 13.5-inch gun burst at the seventh discharge, shows that the criticism against the wire-wound guns is well founded, and that it is, in fact, not true that the latter have a circumferential strength greater than that of the hooped guns.

That the wire-wound guns are very defective as regards longitudinal strength is a matter which is now so well known that there is no need to demonstrate it, and in connection therewith it will be sufficient for me to refer to the important article which was published on this subject in the February-March number of the *Journal of the United States Artillery*.

As regards the circumferential strength, I beg to call your attention to the two important essays which were published in the "Memorial de l'Artillerie Navale" of 1912 by the ordnance and naval engineers Messrs. Léon Coupaye and Pierre Malaval.

Those two gentlemen have exhibited, by different methods and procedures, the following principle: "Whatever may be the system according to which a compound gun is constructed, whether it is hooped or wire-wound, the internal pressure which it can resist without altering its shape permanently has as its upper limit the value of the limit of elasticity of the metal of which its internal tube is manufactured."

Thus, for instance, a gun the inner tube of which is manufactured of a metal with a limit of elasticity of 40 kilos, cannot resist, without a permanent deformation, an internal pressure exceeding 4,000 kilos per square centimeter (56,891 pounds per square inch). This limit of internal pressure can, however, be reached only in case the internal tube is of infinite thickness. It is less in practice, and decreases with the thickness of the tube.

In the wire-wound guns, the internal tube is of small thickness and strongly compressed by the steel ribbon surrounding it externally. The limit of elasticity of the ribbon is superior to that of the tube, and consequently under a given pressure, the latter suffers an elongation greater than that of the ribbon. When the entire arrangement returns to its state of repose, the tube can no more retake its former dimensions, because it does not find the necessary space to do so and, consequently, contracts or breaks. The contraction of the internal diameter of the wire-wound guns is a well-known phenomenon which I have personally ascertained; it has been, may be, and will be the cause of the jamming of the projectile in the bore, and of the consequent bursting of the gun.

I think that to this cause must be attributed the bursting of the English 13.5-inch gun, as well as that of the American 14-inch gun, and it seems to me that these two accidents, which took place within a few days of each other, must give rise to serious thoughts.

Torino, Italy. ETTORE BRAVETTA,

Captain Italian Royal Navy (retired).

[The theory of our correspondent regarding the cause of the bursting of the 13.5-inch gun is decidedly interesting. He is wrong with regard to the American 14-inch gun, whose failure was due to other causes which we are not at liberty to disclose.—EDITOR.]

Capt. Roald Amundsen who discovered the South Pole on December 14th, 1911 and who was at one time only five days journey from the ill fated Scott party

Sir Ernest Shackleton who was Scott's second in command on the expedition of 1901-1904 and who led a party of his own to a point within 97 miles of the South Pole in 1909

Capt. Robert Falcon Scott who discovered the South Pole on January 18th, 1912 and who perished with four companions on his return journey

Three explorers who have made Antarctic history

The Scott Expedition and Its Tragic End

A Sacrifice Made for Scientific Ideals

IN the desolate, icy waste of an unexplored Antarctic country Capt. Robert Falcon Scott gave up his life, after having reached the South Pole. He died a true hero of science. There was no buried treasure to seek in those untrodden southern snows—nothing but everlasting fame. Only those who are engaged in scientific research can understand the ideals of a man who willingly cuts himself off from the world for a period of three years and perishes in a blizzard—for what? For meteorological information, for geological data, for light on the fauna and flora of a cold, white, silent land that will probably never be peopled, for a handful of rocks and fossils that will show the relation of the Antarctic Continent to South America and Australia, for a study of the southern atmosphere and the southern seas, in a word, for things that are infinitely removed from gold hunting.

Let it not be supposed that the cause in which Scott died was the mere attainment of the South Pole. If that "athletic feat," as it has been termed, were the only object of polar exploration, scientific societies would not contribute a penny to the equipment of an expedition. Nor would men of Scott's and Shackleton's attainments be interested in it. A polar dash makes good newspaper reading, but your scientific geographer looks primarily for some addition to the world's knowledge.

The Great Unexplored Antarctic Continent.

Until the close of the nineteenth century there was no part of the world about which less was known and none about which so little interest was manifested as Antarctica. The reason is to be found in its distance from the centers of wealth and thought, in its dearth of animal and vegetable life, and in its unpeopled state. The game hunter, the dare-devil explorer seeking adventure, found little to attract him in that bleak and barren country. It was a region that held a fascination only for the scientifically inclined man, and hence we find that most of the men who have braved its terrific blizzards have been men of the finest scientific type.

Definite knowledge of the Antarctic regions was acquired very late in the nineteenth century. Indeed, to Capt. Scott belongs the credit of having first penetrated Antarctica during his first expedition of 1901 to 1904. Before that time geographical knowledge of the South Polar regions was confined largely to sea approaches. To be sure, Palmer Land with its associated islands, the coast of Victoria Land with the adjacent Ross Sea, and to a lesser extent, the coast of Wilkes Land had been explored; but of the great Antarctic continent as a whole, practically nothing was known before Scott's first expedition returned. True, the examinations of the Belgica, the Francais, and the Pourquoi Pas showed that Palmer Land extended away to the southwestward along the southern confines of the Pacific Ocean, and the German Gauss Antarctic Expedition confirmed the discoveries of Wilkes, made in 1840 and so long discredited. But the first who really scaled the Great Barrier and gave us some idea of a continent whose present unexplored and unvisited extent is still twice the area of Europe was Scott. Thanks to his studies, supplemented by those of Shackleton, we know that in former geologic times the continent was probably connected with Africa, South America, Australia and New Zealand, although not with all of them at the same time. The first phase of any journey which has for its object the exploration of this vast territory must be over the plateau of the Great Barrier, the second a climb through mountain passes, and the third a traverse of a lofty inland plain. Not all the explorers who managed to ascend the Great Barrier could take any means of transport with them. Sir Ernest Shackleton had to advance with the unaided efforts of man alone. His party started on the second phase with full loads, and achieved what is probably the maximum that could be accomplished under such circumstances. Amundsen was able to use dogs because of the more or less favorable conditions which he encountered. Perhaps to that fortunate circumstance his success may to large measure be attributed. But even if ponies, dogs or motor sledges can be used, it must be remembered that the last phase of the journey, owing to the height of the plateau, must inevitably be accomplished under climatic conditions which for severity are unequaled either in the Arctic or Antarctic regions. Polar exploration must be conducted with a technique of its own, a technique that differs at both extremities of the earth for the simple reason that the topographical conditions are not the same. In the north we find islands and a polar sea. In the south an austral continent surrounded by an enormous floating ice cap which is called the Great Barrier and which covers probably more than 150,000 square miles of the Antarctic Ocean. Sledging is, of course, necessary in both regions. In the north it is not possible to travel by sledge over the frozen sea except during a short period in spring. In the south sledging is more or less possible at all seasons, except that the meteorological conditions are more favorable at some times than at others.

The Importance of Equipment

Next to the personality of the leader, equipment is the most important element in the success of polar exploration. The Japanese expedition under Lieut. Shirase failed because of its poor outfit. Amundsen was not equipped nearly so well as Scott. Personal courage and will counted for more in his

The South Pole lies on a lofty eminence. How it was attained by Amundsen on December 16th, 1911, and by Scott on January 18th, 1912, is indicated on this map, together with Shackleton's course in 1909.

Amundsen's dog teams and sleds plodding along toward the Pole. This picture was taken by Amundsen only a few miles from his goal.

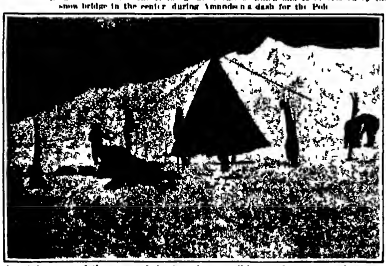
Photograph of Lieut. Helmer Hansen taken by Capt. Amundsen at the South Pole with one of the dog teams.

case than anything else. Lieut. Filchner, the head of the German expedition now in the South Polar regions, conducted his undertaking with true German deliberateness. First he carried out an elaborate campaign of oceanographic work out in the South Atlantic, and then a series of very interesting meteorological observations with sounding balloons in South Georgia. Finally, on the 10th of December, 1911, his ship the "Deutschland" set sail for Antarctica, where he expects to remain until the winter, that is the southern summer 1913-14. The "Deutschland" is equipped with wireless.

It may be that Lieut. Filchner's expedition is better equipped than that which Capt. Scott led. On the other hand, we are informed that Scott spared no time, energy or money in order to fit out his part. By popular subscription the sum of $200,000 was raised. He selected for his ship the "Terra Nova," the largest and the strongest of the old Scottish whalers. Built at Dundee in 1884, she is 187 feet in length and 31½ feet in beam, and is considered the best ship ever launched for the Greenland whale trade. Of late years, because of a decline in the whaling business, she has been engaged in seal hunting in the northern waters, sailing from St. Johns, Newfoundland.

The "Terra Nova," however, has not confined herself to the humdrum of trading. In 1903 she was purchased by the Admiralty as a relief ship for the "Discovery" expedition, and after being considerably strengthened she duly made her appearance in Ross Sea. The year 1905 saw her in the service of a North Polar expedition on a visit to Franz Josef Land. Thus she has ranged from the great ice barrier in the south to the North Polar pack—from extreme to extreme of the navigable waters of the globe. The size and strength of the ship make her a fitting receptacle for the extensive equipment which it is necessary she should carry for success.

In the foreground can be seen one of the great crevasses which had to be crossed by the snow bridge in the center during Amundsen's dash for the Pole.



Framheim, one of the camps of the Amundsen expedition used as a base of supplies.

Scott's Equipment.

In equipping his expedition Capt. Scott displayed painstaking care. He laid great stress on the fact that the newly devised motor sledges offered a new means of ice travel, and three such sledges were stored in the hold of the "Terra Nova," as well as an equal number of the more familiar dog sledges. In a final statement before the expedition started Capt. Scott thus summarized the difficulties of Antarctic travel:

"The problem of reaching the South Pole from a wintering station is purely one of transport. The distance to be covered there and back is about fifteen hundred miles. The time at the disposal of an explorer in a single season never exceeds one hundred and fifty traveling days. An average of ten miles a day can easily be maintained by men of good physique, provided adequate transport facilities are made.

"There are three means by which the traction for heavy sledge loads can be provided, viz. ponies, dogs, and motors. As a result of two years' experiments, a motor sledge has been evolved which has undergone satisfactory trials on the snows of Norway. A motor was recently taken on Mr. Shackleton's expedition, and it is instructive to note that it was found possible to run it in the lowest temperatures. Its use on a prolonged journey was prohibited only by the fact that its wheels were not sufficient to support it on the soft snow of the Barrier.

"The plan for the journey to the south pole from King Edward VII Land includes the use of the three means of sledge traction described. Ponies will be taken in sufficient numbers to insure a thoroughly adequate supply of food and will be used for transport to the foot of the glacier; a dog team with a relay of men will transport the loads over the glacier surface, and a picked party of men and dogs will make the final dash across the inland ice sheet. Motor sledges will be used according to their proved capacity as a main agency or useful auxiliary to the transport plan. If they reach the foot of the glacier there is little doubt that they will ascend it

The juncture of the Great Barrier and King Edward VII Land. The Barrier here appears about 300 feet in height.

One of the camps established by the Amundsen South Pole expedition on the way to the Pole.

On the way to the South Pole.

and greatly simplify the difficulties of the remaining journey. If they fail to reach the glacier they will, at least, as far as they will have taken relieve the ponies and dogs of the weights, and increase the safety of the return journey as they can be cached, when no longer available, to await the return of the party."

Scott's Programme

In a lecture delivered in London before his departure, Scott presented the following programme:

HOW CAPT. SCOTT MAPPED OUT AS FAR AS WAS POSSIBLE THE TIME TABLE OF THE BRITISH ANTARCTIC EXPEDITION

Departure from London	June 1st, 1910
Cardiff	June 15th 1910
Cape Town	August 1st 1910
Melbourne	September 11th, 1910
New Zealand	October 17th 1910
Leave New Zealand	end of November, 1910
McMurdo Sound	end of December 1910
Landing of winter hut and provisions of western party (twenty two to twenty five persons in number)	December 22nd 1910
Starting off of this party	about January 21st, 1911
King Edward's Land reached, if possible, early in	February, 1911
Establishment of second hut and traveling equipment for party of six men on King Edward's Land	February, 1911
Caches of provisions to be left on edge of Great Ice Barrier to form link between eastern and western parties	February 1911
"Terra Nova" to turn northward about	February 21st 1911
Investigation of the pack in the region of the Balleny Islands, and to proceed to the westward through or to the south of those Islands	March 1911
Depots laid well to the south on the Great Ice Barrier	April 1911
Start for the South Pole to be made during the month of	October 1911
Barrier to be traversed and the Beardmore Glacier ascended	during October and November 1911
Upper plateau to be reached	early in December 1911
South Pole to be reached if possible on December 22nd 1911	

Adverse conditions prevented him from living up to the schedule. He was delayed from four to six weeks in making the preparations for his polar dash.

Capt. Scott (seated) and his first officer, Lieut. Evans.

The hut in which the 1910 expedition lived after the ship landed them on the Antarctic continent

The internal arrangements are here only approximately given as the final divisions of the hut were settled on the Antarctic snows.

The Journey to the Pole.

Scott's actual start for the pole began on November 2nd, 1911, later than he expected. His plans and hopes were last described by himself, and the version was brought back by the "Terra Nova."

"The pony party consisting of myself with Wilson, Oates, Bowers, Cherrard, Atkinson, Wright, Evans, Crean and Keohane will start about November 1st. Independently of the success of the *motors*, ponies will be worked with light loads in easy marches to Corner Camp, with full loads and easy marches to One Ton Camp and with such pressure as necessary thereafter. Dog teams starting will rejoin us at One Ton Camp and help to advance loads. By these means we hope to get thirty units of food to the foot of Beardmore Glacier, a unit being a week's provision for four men. Then with three divisions of four men and twenty-one units of provisions, I hope to extend the advance to the required distance if the weather conditions are not wholly unfavorable.

Of the ten remaining ponies one is unreliable and one doubtful, the remainder being in very fine form. Officers and men are in splendid health and eager to go forward. Owing to my decision to postpone there is an obvious chance that the most advanced southerly party will be unable to reach the Terra Nova before she is forced to quit the Sound. Under these conditions, having regard to important scientific work done and facilities offered for further work, I have decided to maintain the station for a second year. The majority of the shore party will probably remain, but details depend upon the date of our returning from our journey, on home news and the extent of fresh transport provided."

On November 24th Capt. Scott wrote that the party arrived at Corner Camp. Just before One Ton Camp was reached the dog sled party caught up with Capt. Scott's party and they journeyed in company. They passed the abandoned motor sleds, and when they found the motor party waiting at latitude 80½ they learned the motors had been left behind because of the overheating of the air-cooled engines.

Capt. Scott, on January 3rd, 1912, when he was one hundred and fifty miles from his goal, wrote of his plans in a message he sent back. He said:

"I am going forward with a party of five men, sending three back under Lieut. Evans with this note. The names and descriptions of the advance party are: Capt. Scott, R. N.; Dr. Wilson, chief of the scientific staff; Capt. Oates, Inniskillen Dragoons, in charge of the ponies; Lieut. Bowers, Royal Indian Marine, commissariat officer; Petty Officer Evans, R. N., in charge of sledges and equipment.

"The advance party goes forward with a month's provisions and the prospects of success seem good, providing the weather holds and no unforeseen obstacles arise."

The Tragic End.

Capt. Scott and the four men with him reached the pole on January 18th, 1912, but on the return journey all perished. Their bodies were not found until a searching party sent out on October 30th discovered them on November 12th, nearly eight months after the disaster, in latitude 79 degrees 40 minutes south and longitude 169 degrees 23 minutes east. Evans died from concussion of the brain on February 17th, 1912. Oates from exposure on March 17th, 1912. The remaining three men made their way back to within 155 miles of Cape Evans, when they were caught in a blizzard that must have lasted nine days, and were overcome about March 29th within eleven miles of the shelter and supplies at One Ton Camp.

The relief expedition recovered the records of Scott. He had found the tent and documents left by Capt. Amundsen when the Norwegian left the pole about a month earlier.

Scott's total distance to the pole and back was 1,842 statute miles.

The death of Capt. L. E. G. Oates of the Sixth Inniskillen Dragoons was heroic in every sense of the word. Despite his badly frostbitten feet and hands, he struggled on manfully. On March 16th his comrades knew that he was doomed. For weeks he had suffered intensely without complaint. No wonder that Scott wrote in his diary:

"He was a brave soul. He slept through the night hoping not to wake; but he awoke in the morning. It was blowing a blizzard. Oates said: 'I am just going outside and may be some time.' He went out into the blizzard and we have not seen him since."

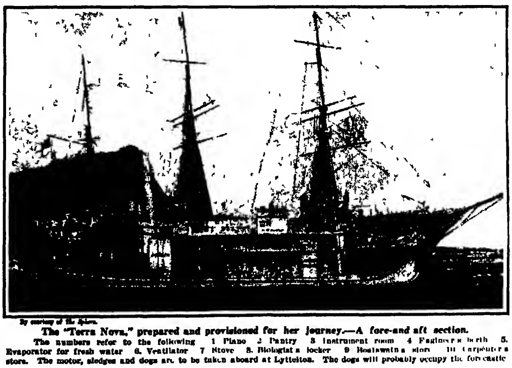
There is only one construction to be placed upon this passage. Oates knew that he could not live; he knew that as a sick man he was an impediment and the chances for the survival of the rest were better with himself out of the way. Bravely he stepped out of the tent and into the blizzard never to be seen again.

In the last tent pitched by the party a final message by Scott himself was found. Written with the shadow of death upon him, its pathetic appeal has deeply moved the civilized world. We reprint it here from the columns of the New York *Times*.

Message to the Public.

"The causes of this disaster are not due to faulty organizations, but to misfortune in all the risks which had to be undertaken. One, the loss of pony transport in March, 1911, obliged me to start later than I had intended and obliged the limits of stuff transported to be narrowed. The weather throughout the outward journey and especially the long gale in 83 degrees south stopped us. The soft snow in the lower reaches of the glacier again reduced the pace.

"We fought these untoward events with will and conquered, but it ate into our provisions reserve. Every detail of our food supplies, clothing and depots made on the interior ice sheet and on that long stretch of 700 miles to the pole and back worked out to perfection. The advance party would



By courtesy of The Sphere.

The "Terra Nova," prepared and provisioned for her journey.—A fore-and-aft section.

The numbers refer to the following: 1. Piano. 2. Pantry. 3. Instrument room. 4. Engineer's berth. 5. Evaporator for fresh water. 6. Ventilator. 7. Stove. 8. Biologist's locker. 9. Boatswain's store. 10. Carpenter's store. The motor, sledges and dogs are to be taken aboard at Lyttelton. The dogs will probably occupy the forecastle.

have returned to the glacier in fine form and with a surplus of food but for the astonishing failure of the man whom we had least expected to fail. Seaman Edgar Evans was thought to be the strongest man of the party and Beardmore Glacier is not difficult in fine weather. But on our return we did not get a single completely fine day. This with a sick companion enormously increased our anxieties. I have said elsewhere that we got into frightfully rough ice and Edgar Evans received a concussion of the brain. He died a natural death but left us a shaken party with the season unduly advanced.

But all the facts above enumerated were as nothing to the surprise which awaited us at the Barrier. I maintain that our arrangements for returning were quite adequate and that no one in the world would have done better in the weather which we encountered at this time of the year. On the summit in latitude 85 degrees to 86 degrees, we had minus twenty to minus thirty. On the Barrier in latitude 82 degrees 10,000 feet lower we had minus thirty in the day and minus forty-seven at night pretty regularly with a continuous headwind during our day marches.

These circumstances came on very suddenly and our wreck is certainly due to this sudden advent of severe weather which does not seem to have any satisfactory cause.

I do not think human beings ever came through such a month as we have come through and we should have got through in spite of the weather but for the sickening of a second companion, Capt. Oates, and a shortage of fuel in our depots for which I cannot account and finally but for the storm which has fallen on us within eleven miles of the depot at which we hoped to secure the final supplies. Surely misfortune could scarcely have exceeded this last blow!

We arrived within eleven miles of our old One Ton Camp with fuel for one hot meal and food for two days. For four days we have been unable to leave the tent, the gale blowing about us. We are weak.

Writing is difficult, but for my own sake I do not regret this journey which has shown that Englishmen can endure hardships, help one another and meet death with as great a fortitude as ever in the past. We took risks. We knew we took them. Things have come out against us, and therefore we have no cause for complaint but bow to the will of Providence, determined still to do our best to the last.

But if we have been willing to give our lives to this enterprise which is for the honour of our country I appeal to our countrymen to see that those who depend on us are properly cared for. Had we lived I should have had a tale to tell of the hardihood, endurance and courage of my companions which would have stirred the heart of every Englishman.

These rough notes and our dead bodies must tell the tale but surely surely a great rich country like ours will see that those who are dependent on us are properly provided for. (Signed) R. Scott

March 25th 1912

Campbell's Expedition and Its Relief

An expedition under Lieut. W. A. E. Campbell which had been sent to make geological investigations to the east of Cape Evans, also passed through perilous experiences, but returned safe and well. The "Terra Nova" had been unable to take the men off the year before on account of ice and they were compelled to spend another winter in the Antarctic. In this party were Dr. Levick, Priestly, Abott, Browning and Dickason. A gallant attempt to relieve Lieut. Campbell was made in April but the relief party was stopped by open water. Campbell and his companions were eventually rescued by the very searching party that found the body of Scott.

The escape of Lieut. Campbell and his northern party was miraculous. The men existed in absolute darkness except for the faint gleam of a seal blubber lamp. The supply of provisions was soon exhausted and thenceforward they had to live entirely on seal meat and to endure extraordinary hardships.

The Condition of Amundsen and Scott Contrasted.

Amundsen and Scott must have passed each other in the Antarctic some time during Christmas week, 1911. Amundsen rejoicing in his victory was speeding away from the Pole with good fortune attending each day's journey. Scott still hopeful, was forging stubbornly toward his goal passing from the 86th to the 87th parallel and disposing his records and supplies so that when the last auxiliary detachment of his party started back under the guidance of Lieut. Evans he would be ready for the final dash. Scott and Amundsen must have been near each other on December 28th 1911 when they were a little more than 200 miles from the Pole and about 150 miles apart. At the rate of Amundsen's returning speed he could easily have crossed the intervening ice and snow and met Scott in less than five days traveling.

Contrast Amundsen's return journey with that of Scott's. Here is Amundsen's account:

> On the return journey we had not a single day's rest. We did not even rest on Christmas day but passed on day after day through all weathers. There was little that was adventurous about the trip. But it was very hard work.

He suffered no privations, for he tells us:

> Of real hardships in the way of food on the pole journey there were none. Rather the reverse, for when my companions reached the ship they were almost fat and could not eat as much as when they started. The dogs, too, were fat and that they had lived well during the last part of the journey was shown by the fact that they would hardly touch the seal meat which was lying in large quantities about the base camp.

Amundsen had full rations all the way, but in that ultimate full rations are a very different thing from having as much as a man can eat. "There seemed little limit to one's eating powers when doing a hard sledging journey," says Amundsen. "However, on the return journey we had not merely full rations, but as much as we could eat from the depots, after passing 80 degrees."

Although Scott himself, Shackleton and Amundsen had all made extensive researches in the vicinity of the South Pole much still remains to be done.

The Scott Expedition, 1901 to 1904, discovered what is now known as King Edward VII Land, extending east of the Great Barrier from 152 degrees to 157 degrees east longitude. Following the Great Barrier to 82 degrees 17 minutes south Scott ascended the glacial covering to the overlying plateau, and after a journey of 300 miles reached an elevation of over 9 000 feet, a point in 77 degrees 30 minutes south and 147 degrees east longitude.

Shackleton's Expedition.

Shackleton's Expedition of 1907 to 1909 penetrated at the same place that Scott had previously entered, and proceeded up the western border of the ice field along the route which Scott had pursued. Shackleton thus reached a great glacier named Beardmore Glacier, coming down from the highlands to the westward. In 127 days Shackleton and his parties traveled 1,755 miles, reaching on January 9th, 1909, a glacier-covered plateau about 11,000 feet above the ocean in 88 degrees 23 minutes south latitude at 162 degrees west longitude within ninety seven miles of the Pole. In extent and importance the discoveries made by Shackleton have not been surpassed by any other single expedition. Perhaps the most interesting discovery made by Scott was that coal existed in large quantities in the Antarctic continent—unmistakable evidence that a land now frigid and barren once bloomed in tropical luxuriance. While Shackleton's journey to the Pole was in progress one party of the expedition climbed Mount Erebus and another reached the south magnetic pole and located it in 72 degrees 25 minutes south and 155 degrees 16 minutes east longitude in a position forty miles distant from the point deduced by the first expedition of Scott.

Amundsen's Contribution to Polar Geography

Despite all the haste with which he proceeded, Amundsen made important additions to our knowledge of the Antarctic continent, particularly in that sector of the earth's surface extending from the South Pole to the eightieth degree parallel of latitude between the meridians 100 degrees and 180 degrees west of Greenwich. He rather confirmed the view that the Pacific Ocean must be bounded on the south by a coast of the "Pacific type" the main characteristic of which is that the trend is determined by mountain ranges running parallel to the shore. The type is well exemplified in New Zealand on one side and by the Andes of South America on the other.

Amundsen's Antarctic venture came as a great surprise to the world. He left Norway in June, 1910, in the "Fram" seemingly with the intention of sailing around Cape Horn and through the Pacific Ocean and then Bering Sea into the Arctic Ocean. Upon rounding Cape Horn however he sailed to the westward across the South Pacific and made a landing at Whale Bay on the ice sheet covering Ross Sea. This place is in King Edward VII Land, near the eastern end of the ice front and opposite that point on Ross Sea from which Scott and Shackleton made their successful entrances into the interior. In less than a month the southbound expedition had cleared that vast plain of floating ice which flows down from the great mountains of the interior and covers the southern part of Ross Sea, throughout an area of 20 000 square miles, with an ice sheet approximately 800 feet in thickness. By a series of wonderful marches Amundsen reached the South Pole on December 16th, 1911. He followed the 164th meridian (west) to a mountain range in about 85 degrees south latitude. Here his party crossed Devil's Glacier between mountain peaks about 15,000 feet high. The glacier led to the South Pole plateau, about 10 500 feet elevation entirely ice covered. The route developed was new and independent.

Naturally one cannot help comparing Scott with Amundsen. There was a marked difference in their immediate motives. Unquestionably the attainment of the South Pole was the primary object of Amundsen's undertaking in the Antarctic, though, as we have previously pointed out editorially, this broad minded leader did not consult his own taste in the matter. He made a deliberate concession to popular ideals for the purpose of winning financial support toward an enterprise that did not, in itself, strongly appeal to the public—namely, his proposed five years' drift across the North Polar basin. Similar devious means to philosophic ends have often been resorted to by scientific men.

Not for many months will we learn anything really definite of the scientific results attained by the Scott expedition that terminated so tragically. Enough evidence is at hand to warrant us in stating that one of the auxiliary parties, at least, conducted researches that are invaluable, and that will illuminate the dark subjects of Antarctic meteorology, geology, oceanography, geography, and biology. Indeed, there is every reason to believe that from a scientific point of view the Scott expedition was even more brilliantly successful than that led by Shackleton.

One-man Broadside Control

VICE-ADMIRAL SIR PERCY SCOTT, the famous gunnery expert, has invented, and the British Admiralty, after long and severe trial, has adopted an apparatus for improving naval gunnery, by which astonishing results have been attained. The gear, known as a "fire director" was fitted in the super-dreadnought "Thunderer," armed with ten 13.5-inch guns, and this vessel carried out a series of comparative trials with a sister ship, the "Orion," fitted with the "fire control" system previously in general use. Firing in rough weather at a range of 10,000 yards, at an ordinary battle-practice target (90 feet long and 30 feet high) the most extraordinary results were obtained, the "Thunderer" making four times as many hits as the "Orion," the average of the former vessel being eighty per cent of hits to rounds fired. The tests were carried out in the presence of a large committee of naval officers, including Rear-Admiral Peirse, an ex inspector of Target Practice, Rear Admiral Browning, the present inspector, and a large staff of specially selected naval gunnery experts. As a result of the tests it has been decided to fit the apparatus to all ships of the dreadnought type at an estimated cost of $2,500,000, while the inventor of the system has been honored with a baronetcy.

The greatest precautions have been taken by the British Admiralty to prevent the details of the new system from being made public, and this is very significant when it is recalled that all previous inventions of Sir Percy Scott have been patented, and, therefore, published. In its essential features, however, the "fire director" resembles a similar apparatus which was in use in the muzzle-loading era, when many of the battleships which were built carried from six to a dozen heavy guns of the same caliber. This was invented by Capt. Moorsom, of the British Navy, and, to quote from a work on "Naval Gunnery," by Capt. Garbett, was an apparatus "by means of which the bearing and distance of the target and the heel of the firing ship were all determined, and the guns laid accordingly, it was generally fixed on the upper deck, over the center main deck gun, or other convenient position, and the signal or order to fire was given by the officer attending it as soon as he found the object coming on with his sights." Many scientific and mechanical advances have, of course, been made since this apparatus was invented in 1850. Instead of the officer in charge of the director passing along directions to the captains of the guns by word of mouth, he directs the guns himself electrically under Admiral Scott's system, and instead of giving an order or signal to fire," he fires himself by pressing a button and completing a circuit. All that the guns' crews have to do is to clean out the guns after each round and to load them for the next.

It has been stated that the "Thunderer" while undergoing the tests, fired several concentrated and simultaneous broadsides. It is understood, however, that the Scott apparatus is such that there is a momentary interval of time between the firing of each pair of turret guns, so that the structure of the ship is not called upon to bear the absolutely simultaneous discharge of ten guns, each with a muzzle-energy of 69,000 foot tons.

The fire-director is situated in an elevated position on the foremast as in the case of the fire control apparatus. The obvious drawback to the system is that if one shot misses the whole must miss, but on the other hand, if one strikes home nine others, or as many others as there may be on the broadside, strike home as well, and the ship has not yet been built which could stand the attack of ten 1,250-pound shells simultaneously. The thorough tests carried out by the British Admiralty show that four out of every five broadsides can be depended on to reach the target.

The Current Supplement

IN the current issue, No. 1938, of the SUPPLEMENT, R. H. Reid discusses the advantages of the heavy-oil engine for marine service.—H. T. Kalmus points out the important relation of research to the conservation of our natural resources.—L. C. Talmage, in an illustrated article, describes the extensive harbor developments of Texas City.—Suspicion has become centered on the stable fly as the chief carrier of infantile paralysis, according to a paper by Mr. C. T. Brues.—The snares and pitfalls of "beauty doctoring" are laid bare by Dr. H. Greeley.—This issue brings an important article by H. F. Smith on the chemical and mechanical aspects of the manufacture of producer gas.—Capt. W. I. Chambers call our attention to the importance of a National Aerodynamic Laboratory for the United States.—Spices are not merely useless luxuries or even mere appetite-stimulants—they have antiseptic properties, as has been shown by Hoffman and Evans.

Painting the Wonders Under the Sea

An Artist Who Works Under Water

By Charles M Carroll

MR. Z. H. PRITCHARD an artist now working in California devotes his life to painting pictures under water. He holds that it is impossible to catch the colors and what might be called the atmosphere of submarine scenery by any method of observation from the surface. Even when the disturbing effect of the broken surface of the water is eliminated by using a glass-bottomed boat or tube everything appears unnatural and distorted to the beholder. Mr. Pritchard goes down to the bottom of the ocean wearing a diver's helmet, and makes sketches on waterproof paper with waterproof crayons. The paintings are then completed in his studio.

Mr. Pritchard is an Englishman by birth. When still a boy he made for himself a pair of water-tight goggles, similar to those worn by the famous pearl divers of the South Seas. These goggles are merely bits of cow horn cut and shaped to fit the eyes. They allow a small space of air between the eyes and the water so that one can see very well. With these goggles the young man studied the landscapes under water with a clear vision. His imagination had been fired by Jules Verne's "Twenty Thousand Leagues Under the Sea," but he speedily discovered that it was impossible to shoot birds from the sea bottom as Verne asserted, as the sky is rarely glimpsed by the diver and then only by looking directly upward, for at a moderate angle the surface becomes a gigantic silver mirror reflecting the silent cities of coral and the lone, grotesque figure of the diver.

Mr. Pritchard became a decorator in England and a very successful one. He had preserved a few sketches made from memory of the scenes under water and showed them to some critics but when his fellow artists ridiculed his work he became discouraged.

About this time his health failed, and his doctors ordered him to go to Egypt. Instead he went to

Mr Pritchard ready for work when using the "diver's goggles," the latter shown suspended about his neck.

Coral-eating chaetodons, off Tahiti

Painting showing sand heaps on the bed of the sea.

Tahiti one of the South Sea Islands where he learned the most wonderful coral formations in the world were to be found. Arrived there he decided to take up actively the work of painting the under-water world.

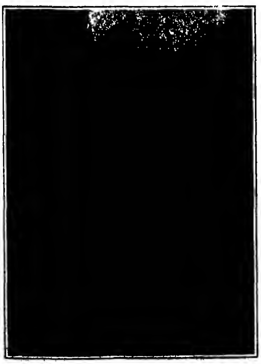
His process at first was comparatively crude. He would go out in his boat with his helpers, find his country with a glass-bottomed box and descend by means of weights hooked to his waist. Then he would make mental notes of the rock or coral formations, ascend and paint them. But this method proved unsatisfactory. He wanted to make actual sketches under the water.

After seemingly endless experimenting he discovered a way of making waterproof paper by soaking extra heavy drawing paper in cocoanut oil and draining off the surplus. This after drying proved to be a good working surface. Mr. Pritchard fastened it to plate glass which served as his drawing board by means of surgeon's tape in order that the water might not ooze under the paper and wrinkle it. He used Raffaelli crayons, semi-solid oil paints which are especially adapted to submarine painting.

After putting on his diving dress and goggles, he would take a good breath and lower himself down in the water using a heavy lump of coral attached to his belt by means of a hook to keep him down. Arrived at the bottom he would sketch from 30 to 45 seconds then unfasten the piece of coral and ascend for breath. The coral was then drawn up by means of a rope for another descent. In this way he was able to complete his sketch after a number of descents. Nowadays he uses a diver's helmet and is able to complete his sketch in one descent.

Thus he works, clad in his clumsy diving suit sitting on a rock and surrounded by the wonderful tropical fish. Of these fish Mr. Pritchard is enthusiastic. He tells of many varieties, from some so tiny that many of them together can be carried on his thumb nail to huge monsters that drift silently and ominously past. There are the bizarre coral-eating chaetodons, the

(Continued on page 18)



Coral formations in the South Sea, the most wonderful in the world.

Safety Lathe Dog

THE accompanying engraving shows two forms of lathe dogs one the common form and another the improved form adapted to avoid danger of injury to the operator of the lathe In the common form of lathe dog the set screw is disposed on the opposite side of the eye from the arm that engages the face plate With this construction there is always the danger to the operator of being struck by the sharp edges of the head of the set screw or by the projecting arm of the dog In the improved form of lathe dog, this danger is avoided by having the arm curved around toward the set screw so as to serve as a shield for it Thus it will prevent the sleeve or clothing of an operator from being caught by the set screw and even if the operator's hand is struck by the arm, the blow will be more in the nature of a push, owing to the curved form of the arm.

Safety lathe dog

Waste Steam Detector

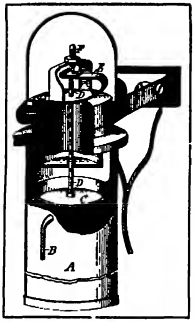
A GREAT many firemen on locomotives labor under the impression that the hotter they keep their fires the better firemen they are Hence they force their steam up to such a pressure as to keep the safety valve constantly popping or blowing off not realizing that the steam which pours out represents an actual waste of water and fuel It is calculated that it takes a quarter of a pound of coal to produce the amount of steam that escapes through a valve three and a half inches in diameter for each second of such escapement This amounts to fifteen pounds of coal per minute or approximately half a ton of coal per hour With larger safety valves the weight will be proportionately greater

Heretofore there has been no way of determining how much fuel is wasted in a given time in the operation of an engine, but an inventor has recently designed a device which keeps a record of the time during which the safety valve is blowing off The recording device is kept locked so that it cannot be tampered with and at the end of a run an inspector can unlock the device and determine the exact number of minutes during which the steam was blowing off The inventor claims that from experiments so far made by the use of his device a waste of an average of over two tons of coal has been saved in a ten ton run

The device is attached to the casing of the safety valve as shown in the engraving It consists of a clock mechanism with two concentric, graduated circles, one for the minute hand and one for the hour hand The circle for the minute hand is not only divided into minutes, but it is also marked with the equivalent in the pounds of coal of the steam wasted during the corresponding periods of time Similarly the circle for the hour hand is marked off with the equivalent loss in tons of coal A lever mounted on the device carries, at one end a brush which is adapted to engage the escape wheel of the clock mechanism while a broad blade on the other end rests on the perforated top of the safety valve casing When the valve blows off the steam hits this blade drawing the brush out of contact with the escape wheel and permitting the clock mechanism to run

At the start of a run the instructor sets the clock hand to 12 o'clock and then locks the casing of the clock. At the end of the locomotive run he can determine at a glance the length of time that the safety valve had blown off during the run, and also the equivalent amount of coal that has been wasted by the fireman.

Device for recording the "poppings" of a safety valve.



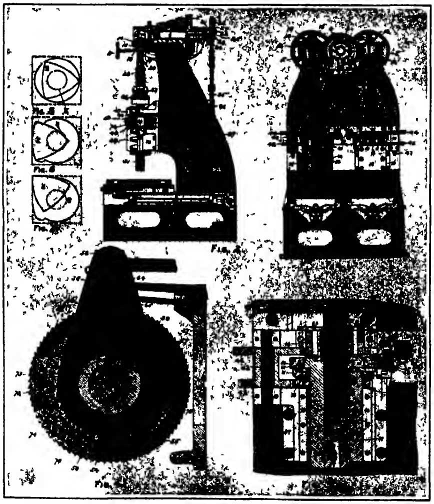
Fire alarm operated by variation of temperature.

A Novel Coaster

A CORRESPONDENT writes that in his city they have smooth asphalt streets and many hills adapted for coasting. Recently the boys have produced, in large numbers, home-made coasters consisting of narrow boards about 4 feet by 2 feet by 2 feet to 3 feet, to the under side of which near each end are fixed one pair of the rollers from a roller skate. On the front of this bar is secured a small packing box extending up about ten or twelve inches, and on top of this is secured a bar which projects laterally at both sides to form a handle. By this, when momentum is once acquired, the vehicle is stabilized so it will maintain its upright position just like a bicycle. Naturally the box obstructs the view of the roadway, and it is believed the idea can be developed into a neat device that can be cheaply produced and should prove a popular and profitable toy.

An Automatic Fire Alarm

THE earliest automatic fire alarms are virtually thermometers arranged to close an electric circuit when a dangerously high temperature was reached. The objection to this form of alarm lies in the fact that it is liable to be operated where there is no fire, as by an accumulation of heat in some badly ventilated spot, or again, it may fail to operate where there is a fire until the fire has gained considerable headway, merely because the temperature at the particular point where the automatic device is located may not happen to rise to the point for which the device was set. The apparatus shown in the accompanying drawing overcomes this difficulty It operates to close an electric circuit when there is a sudden rise of heat In other words, it is not the degree but the variation of temperature that affects the apparatus, provided the variation is sudden The device consists of a metallic chamber A which forms an air reservoir In the side of this reservoir there is a small pipe B, which serves as an air vent Stretched across the upper end of the air reservoir is a diaphragm C which carries a stem D that bears against the leaf spring E forming one terminal of the electric alarm circuit The other terminal consists of the platinum pointed screw F Now in case of a sudden rise of temperature, the air in the chamber A is rapidly expanded so that it raises the terminal E into contact with the terminal F, closing the electric alarm circuit This may be a gong or an automatic sprinkling device In case of a gradual rise of temperature, the expanding air in the chamber A escapes fast enough through the tube B to prevent flexing the diaphragm C The apparatus is so sensitive that the heat of the hands when applied on the chamber A will cause the alarm to ring, and yet if the device be located above a kitchen range, the heat of the range will not cause the alarm to be set off However, if a piece of newspaper be set on fire on top of the range, the alarm will immediately be sounded.



This machine has been designed to meet the great demand for turning out automobile transmission gears quickly and cheaply There is a great demand in factories for a means whereby square, hexagonal, or other polygonal holes may be cut in the gears automatically, rapidly and with accuracy.

Recent Improvements in Machine Tools—III

THE recent enormous activity in the automobile industry has given rise to a great demand for transmission gears to be used on automobiles. There has consequently become a great demand in factories where there is a large output for this industry, for a means whereby square, hexagonal, octagonal or other polygonal holes may be cut in the gears, automatically, rapidly and with accuracy

A H Marsh of Jackson, Mich., has recently patented a machine which is adapted to cut such holes in gears, plates or other work.

As seen in Fig. 1, the machine is a duplex one, the same driving mechanism, including the cone pulley 3, pinion 4 and gears 5, serving to operate the two shafts 6. The

(Continued on page 185)

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Pertaining to Apparel.

FASTENER FOR BUTTONS AND OTHER ARTICLES.—O. D. BALL, 317 Fenimore St., Brooklyn, N. Y. The present invention is a fastener of the friction or tension type and involves a cord having looped engagement with

BUTTON FASTENER.

the articles to be fastened and disks for frictionally gripping the ends of the cord. The device is especially intended for use in fastening buttons to garments made of fur or any heavy fabric to which it may be applied without sewing.

SWEATER OR LIKE GARMENT.—B. I. CAMPE, care of Hecht & Campe, 377 Broadway, N. Y., N. Y. With sweaters having soft collars, as specified for the wearing of links engaging collar flaps, the links are liable to become disconnected from one or both collar flaps, and the collar has a tendency to curl or creep upward, and moreover, when ties are worn with the garment they are usually four in hands, or ties similar to these and the knot of the tie frequently sags, putting a strain on the link tending to pull the buttons of the links through the buttonholes. The invention overcomes all these drawbacks.

COMB AND BARRETTE.—J. A. BUALANDO, 3674 White Plains Ave., Williamsbridge, Bronx, N. Y. This inventor provides a co-operating comb and barrette, the latter being adapted to be held on the comb after the comb has been positioned on the head. The use of the co-operating comb and barrette prevents loss of the barrette or the comb since the parts are held in engagement with each other and also with the person's hair.

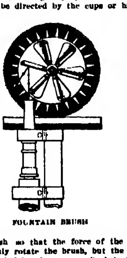
Electrical Devices.

SIGN AND INDICATOR.—P. FICCIO, 1015 Franklin St., Tampa, Fla. In order to indicate the direction in which a vehicle is about to turn, Mr. Ficcio has devised a sign or indicator which may be attached to the rear of a vehicle and which may be operated mechanically to project into view a slide bearing a legend or word showing the direction the vehicle is about to take.

ELECTRIC BELL.—A. LUNGER, care of Edwards & Co., 140th and Exterior Sts., Bronx, N. Y., N. Y. The object here is to so construct the parts in respect to the cover or casing that the cover will more effectually exclude dust, dirt and insects from the parts. By pivoting the hammer at a point closely adjacent the casing side wall through which the hammer extends, the opening in the wall may be made only slightly larger than the hammer, as the hammer will move an almost negligible distance at this point during its oscillation.

Of General Interest.

FOUNTAIN BRUSH.—R. VERNSKE, Tryon, N. C. The object here is to provide a rotary brush with cups or buckets at its sides which is mounted for rotating on a bracket having a clamp by which a nozzle of a standard hose may be secured to the bracket for directing water against the cups or buckets to rotate the brush, these being so proportioned that the water will be directed by the cups or buckets



FOUNTAIN BRUSH.

to the brush so that the force of the water will not only rotate the brush, but the water will be rotated by the cups or buckets to the brush to continue to supply the brush with fresh water.

COMBINED FIREARM AND SWORD.—J. CIMOCHI, 812 So. Main St., Shenandoah, Pa. This invention provides an instrument having co-acting members which may be used simultaneously or independently for offensive and defensive warfare. It also provides a structure on the grip of a sword and so arranges the same that the sword and the firearm may be used independently and that the end of the sword and one end of the guard may be used as sights for the firearm.

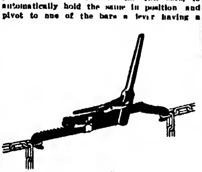
BRUSH.—A. G. CARLINO, 138 W. 64th St., Manhattan, N. Y., N. Y. This brush is provided with bristles for scrubbing and cleaning the hands and nails, and is also provided with a scraper whereby oil and grease may be effectually removed and thus permit effective operation of the bristles in thoroughly cleansing the skin and nails of the hand.

TICKET HOLDER.—H. P. IPSEN, 1490 Crotona Park E., Bronx, N. Y., N. Y. This invention relates to ticket holders and has for an object to provide a simple inexpensive and efficient device which will inclose the tickets for protecting the same but which may be readily ejected one ticket at a time whenever desired.

SECTIONAL DAM AND FLUME.—C. E. HOLMES, 170 River Front, Beaumont, Tex. This invention provides a dam and flume more especially designed for use in brooks and other small water ways for damming the water and for conducting it by the flume to a turbine or other motor and arranged to permit of conveniently placing the dam in position in the water way and to support the flume.

Hardware and Tools.

CLAMP.—C. E. SMITH and J. ROBERTSON, Dutchess Junction, N. Y. The several objects of this invention are attained by disposing two ratchet bars one above the other with a pinion connection between the two bars, to automatically hold the same in position and pivot to one of the bars a lever having a



CLAMP.

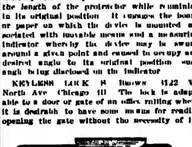
ratchet thereon adapted to fit one of the bars upon the other to be held by the first mentioned ratchet. The invention further disposes on the hook ends of each of the bars a removable facing plate to change the chain clamp into a carpenter's clamp.

PARALLEL PROTRACTOR.—J. I. EVANS, care of U. S. Surveyor General's Office, Reno, Nev. This invention furnishes improved means whereby any angle may be quickly and accurately found. It permits the protractor

PARALLEL PROTRACTOR.

to be adjusted for forming parallel extensions whereby lines may be drawn several times the length of the protractor while remaining in its original position. It engages the board or paper on which the device is mounted associated with movable means and a measuring indicator whereby the device may be swung around a given point and caused to occupy any desired angle to its original position, such angle being disclosed on the indicator.

KEYLESS LOCK.—S. BROWN, 3122 W. North Ave., Chicago, Ill. The lock is adaptable to a door or gate of an office railing where it is desirable to have some means for readily opening the gate without the necessity of inserting a key or working a combination. The



KEYLESS LOCK.

lock has a series of finger keys so arranged that by grasping them in a certain way the bolt will be actuated, but grasping them in any other way will lock the bolt and prevent its actuation.

SAFETY RAZOR.—L. KALTAS, care of Midget Mfg. Co., 178 Center St., N. Y., N. Y. This razor is adapted to be constructed of a size to permit the use of the same as a cuff button, and while the device may be described more particularly with relation to its function as a safety razor it is to be understood that one of a pair of these combined safety razors and cuff buttons may be made of a size and material adapted to be carried in the cuff, the other member of the pair being made to simulate the cuff button constructed as a razor.

COMBINATION DENTAL AND SURGICAL TOOL.—H. A. PARR, 500 Fifth Ave., Manhattan, N. Y., N. Y. This improvement provides a tool more especially designed for cutting superfluous flesh such for instance as grows over the wisdom tooth or other part in the mouth, and for readily slitting or cutting cap crowns preparatory to removing the same.

BEVELED DRILL SOCKET.—A. J. BOONE, care of F. J. Duden, 165 Broadway, New York, N. Y. The invention provides an improved structure designed to receive the shanks of drills regardless of whether or not the same have tangs associated therewith. A further provision is that of a tapering socket formed square or irregular in cross section for receiving a correspondingly shaped shank.

Household Utilities.

STOVEPIPE JOINT.—C. B. SISLER and J. M. DEAVENPORT, Pinkerville, Miss. The invention provides a joint to permit of the firm coupling of the pipe sections which will be particularly advantageous in the case of stovepipes running horizontally, the joint in such a case serving to make a self-supporting connection between the pipe sections that will prevent sagging or accidental disconnection of the sections.

APPARATUS FOR ROLLING TOWELS, NAPKINS AND THE LIKE.—P. G. MERRITT, 1031 Berlin St., New Orleans, La. The purpose here is to produce rolls containing a plurality of separate towels or napkins so constructed that they may be delivered or dispensed one at a time so that the withdrawal of one will result in the partial withdrawal of the next adjacent one in the roll leaving a free end projecting from the dispenser.

Prime Movers and Their Accessories.

ENGINE FEED WATER REGULATOR.—D. C. MOORE, Morrow, Ohio. The present invention is related with patents filed by Mr. Moore bearing Serial No. 509,175 and Serial No. 509,176 respectively. The invention provides simple and efficient means for regulating the length of stroke of a reciprocating pump connected with the water supply to conform with the working conditions of engine boilers and friction of the moving parts in the regulating mechanism is eliminated.

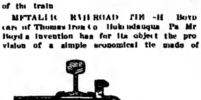
INTERNAL COMBUSTION ENGINE.—L. F. WANAGAN, care of Western Ice Machine Co., 128 W. 2nd St. South, Salt Lake City, Utah. This invention is adapted to use distillate and crude oil in obtaining power and it more particularly relates to an improved firing head. An object is to provide an engine with an improved firing head which will vaporize and ignite crude oil or distillate in a simple and efficient manner without danger of clogging.

CRANKING DEVICE.—R. D. CUMMINS, Middletown, N. Y. This device is arranged to utilize the power of a wound up spring of a spring motor to do the cranking to cause the engine after being started to wind up the spring of the motor and to automatically disconnect the cranking device from the engine shaft to permit the engine to run free of the cranking device and to have said device ready for restarting the engine when desired.

Railways and Their Accessories.

TRIPLE VALVE.—F. K. HUTCHINSON, 1705 So. 1st St., San Jose, Cal. This invention provides a triple valve with means to retard the release of the brakes, and the filling of the auxiliary reservoirs at the front of long trains so that on the rear cars the brakes will in all cases be released and the reservoirs will be recharged on or before the brakes are released and the reservoirs are recharged at the front of the train.

METALLIC RAILROAD TIE.—H. BOYD, care of Thomas Iron Co., Hokendauqua, Pa. Mr. Boyd's invention has for its object the provision of a simple economical tie made of



METALLIC RAILROAD-TIE.

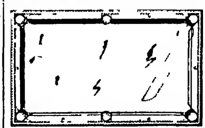
metal and having a maximum of strength for the material used. The construction is such as to provide special strength at the seat of the rail and a fastening device is provided which permits of applying or releasing the rail quickly and of locking the rail firmly to the tie.

RAIL ANCHOR.—J. W. ENRIGHT, 862 Tchoupitoulas St., New Orleans, La. The invention relates to a means for securing railway rails in place and particularly to securing rails from creeping and lateral displacement. This result is obtained by providing a baseplate with an overlying flange between which and the base of the rail a wedge is driven.

RAILROAD TIE.—C. YEADICKE, care of F. J. & J. T. Burns, Suite 7, Trust Bank Bldg., Kankakee, Ill. The invention provides an improved cross tie for railroad rails which is made of metal and for this reason has superior qualities of strength and endurance. The object of this invention is to improve the form and design of metallic ties so as to cheapen their construction and make them more stable and efficient in use.

Pertaining to Recreation.

POOL AND BILLIARD TABLE.—G. S. VAN DE WATER, care of Wallie Dorr Co., 16 Reade St., New York, N. Y. This invention relates



POOL AND BILLIARD TABLE.

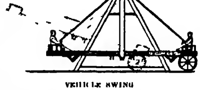
generally to pool and billiard tables and more particularly is directed to an improved cushion construction adapted to occupy different positions whereby the same table is convertible into a pool or billiard table. The principal object is to provide a cushion for use with pool or billiard tables, the said cushion being removably held in position, the improvement residing in the shape of the cushion whereby it may occupy different positions to close the pockets or leave them open, thereby providing either a pool or a billiard table. The illustration is a top plan view which pictures the cushions in position to form a pool table.

Pertaining to Vehicles.

SPRING WHEEL.—V. E. LANE, 288 Park St., Detroit, Mich. This invention relates to resilient wheels which are commonly employed on pleasure and commercial vehicles and among the objects aimed at in the present improvement is to construct a wheel neat in appearance, compact and practically dustproof with respect to movable parts.

TRACE HITCH.—T. J. JOHNSON, Box 38, Allentown, Pa., and J. C. ELLAS, Allentown, Pa. This invention provides a device adjustable to accommodate traces of various thicknesses, to increase the range of adjustment of the length of the traces and to facilitate the operation of fastening the traces in operative position.

VEHICLE SWING.—O. ZIMMERMAN, 6815 South Park Ave., Los Angeles, Cal. The object of the inventor is to provide a mechanical swing arranged to provide an exhilarating exercise and considerable amusement to young and old using the swing, to insure safety in the



VEHICLE SWING.

use of the vehicle swing and to guard against a tendency of producing dizziness of the user. For the purpose named use is made of a suspended link pivotally supporting at its lower end a supporting frame provided at one end with wheels and seats, the wheels being adapted to travel on the ground, on the floor or rails or other suitable support.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles

Where the Motor Bus Beats the Trolley

By J R. Eustis

WHILE the United States leads the world in the use of motor trucks, having more in service than any other two countries combined there is one type, the motor omnibus, in which England, France and Germany lead this country by a wide margin It is hard in fact, for us to really appreciate the extent of the motor bus service now provided in the cities of London Berlin, and Paris.

The largest company operating in London for example now has over 1 500 motor omnibuses in service This is the London General Omnibus Company and its installation of motor vehicles is the largest in the world. This company formerly owned 18,000 horses and over 2,000 horse-drawn buses, but these have now been entirely discarded

This company carried in the past year 210,300 000 passengers, or only about 25 per cent less than the 287 199 629 passengers who rode in the New York subway during the year ending last December The lack of a comprehensive system of surface electric cars in London, of course favors the use of motor omnibuses.

That the motor omnibus has decided advantages over the street car, and will largely displace the latter, is indicated by figures now available for both the London County Council and the London General Omnibus Company The former, operating tram lines under a $90 000 000 capitalization, obtains a route mileage per car of 120 miles per day while the latter, with $11,230 000 capital gets 170 miles per day For February of this year the bus companies' business showed an increase over the corresponding period of 1911 of 21 per cent, while the tram lines gained only 6 per cent The motor omnibuses are therefore, not only proving more popular with the traveling public, but evidently return larger dividends.

What Motor Trucks Have Saved for a Brewer

By Jean E. Blaise, General Superintendent of the Peter Doelger Brewing Co.

WE have sold every horse we owned, we let the last one go May 2nd 1912. Now even our ashes are disposed of by means of a motor truck

We bought our first 5-ton electric truck in 1904, merely as an experiment We did not buy again until 1909 when we bought three A few were purchased in 1910 and in the end of that year we became satisfied that with the improvements in truck design and our better knowledge of scientifically routing out deliveries, the motor truck was a paying business proposition Accordingly in 1911 we bought 35, the majority of them all 5-tons capacity and this year we have already purchased 20 more giving us about 60 electrics altogether Then of course we have 18 gasoline trucks for our extra long hauls.

We sold our first horse in the fall of 1910, and sold more and more as the trucks came into service We have sold 176 altogether as a direct result of installing motor trucks, and I know it has been a wise thing for us to do. We had the best horses and wagons that money could buy and good capable drivers who were with us for long periods, but the motor truck is the only thing for the up-to-date brewer At least for the one who realizes that money saved in distribution is as important as that saved in production We have reduced the cost of delivering beer in Greater New York from 35 cents per barrel to 15 cents per barrel, and this within from 8 to 10 miles from the brewery Our whole delivery system has been revolutionized, and in place of immense stables, we have a fine garage, which has saved us indirectly, half a million dollars in real estate alone.

We had a stable 200 feet wide fronting on East Fifty fifth Street, and back of it three wagon yards and some other buildings, used just for our horse equipment We tore down half of the stable, converting the rest of it to other uses, and built on the ground so released a big bottling plant. In one of the wagon yards we built a garage for our trucks, 85 by 100 feet, and this is all the ground necessary to house 100 trucks, because we only need five stories even for that. The long and short of it was, we were wasting about twenty-eight city lots worth from $15,000 to $20 000 each. And that isn't all the money we saved. In addition, the saving of from 18 cents to 20 cents per barrel on beer delivered, plus the saving on drivers, foots up to between $60,000 and $75,000 per year

We haven't completed nearly all our plans yet Inside of another year, we shall establish four depots in Greater New York, delivering the beer from the brewery to the depot with heavy trucks and distributing it from these centers with lighter power vehicles. By this method, we expect to operate electric trucks exclusively, as we believe electricity is going to supplant other forms of power in the industrial world. Year by year we drive more machinery and appliances in our brewery with electricity, and there are good reasons for doing this. Things reached a point where it cost us 96 cents per day to feed and care for each horse in our service We knew we had to find a solution for that expense or go out of business and that principle applies to other things as well Two men with salaries aggregating $.88 per week care for all our motor trucks, so you see the difference

Cost of Gasoline Truck Service

To the Editor of the SCIENTIFIC AMERICAN

In the SCIENTIFIC AMERICAN of January 18th, we note with considerable interest the article by Mr H W Perry entitled "Teams and Motor Trucks Compared." We beg to take exception to the figures he gives, as he assumes that full loads are always hauled both ways, which is very rarely the case It is very seldom that full loads are carried half the distance the truck travels.

You can readily realize that if the truck starts out with a load of merchandise and begins making deliveries, by the time it reaches its farthest point it will be empty and will return in that condition. With contractors full loads are often carried to destination and then the truck returns empty With breweries and allied industries full loads are often taken to one point and a load of "empties" brought back, and these are the people that generally have the greatest ton mileage

So you will see from this that it is not possible to figure out ton mileage unless the exact conditions are known. This term is often used, and very seldom is it used correctly We consider the cost per mile a much more reliable figure

We also notice "Cost Estimates of Horse and Motor Trucks" by Mr John Ritchie, Jr Our experience is only with a 5-ton gasoline truck, but the writer's experience has been with all the different sized machines from 2 tons to 10 tons capacity, and he has invariably found that a gasoline truck is much cheaper to operate at, say, over 24 miles a day, than is the electric of similar capacity working under the same conditions.

Mr. Ritchie refers to the tests made by

Classified Advertisements

the Massachusetts Institute of Technology. We have the Bulletin No 2 giving these tests, and averaging the figures they give in reference to five-ton trucks, and using the cost for current given us by the New York Edison Company and the cost for insurance rates we compiled the following table

Costs to be Considered in the Operation of a Pierce-Arrow Five ton Truck.

Fixed charges vary and so should be determined by each owner but the following list includes all the necessary items, some of which may be changed or left out

The operating charges are accurate and conservative. If truck receives the consideration it deserves they will be much less.

COST OF TRUCK COMPLETE WITH $300 BODY—$4 800

Interest @ 6%	$288 00
Insurance Fire @ 2¼%	108 00
($.894) Liability $5 000 one person $10 000 one accident	122 00
Property damage $1 000	48 80
Collision 2 2 5% ($25 deduct able coverage)	115 20
Garage @ $25 a month	300 00
Driver @ $21 a week	1 092 00
Helper @ $12 a week	624 00
Fixed charges per year	$2 698 00
Fixed charges per day (1/300 year)	9 00

	Per Mile
Tires (8 000 miles guaranteed for $480)	$0 0611
Gasoline (4½ miles per gal @ 17c)	0 0377
Lubrication (Motor 250 miles per gal @ 60c) (Transmission 5 000 M P G @ 65c) (rear axle 5 000 miles to 3½% gal @ 65c)	$0 0030
Repairs and overhaul (maintained and overhauled every 15 000 miles for $475)	0 0250
Depreciation (truck good for at least 150 000 miles and deducting cost of tires)	0 0287
Operating cost per mile	$0 1555

To find the cost for doing any work add the fixed charges to the product obtained by multiplying the miles run per day by the cost per mile

From this table you will see that it cost 18½ cents per mile to run a five-ton electric truck 24 miles a day and from the second table giving the cost for operating a five ton Pierce-Arrow truck you will find that it costs 53½ cents per mile with our machine to run the same distance

Cost of Operating a Five-ton Electric Truck

based on investigations made by the Electrical Engineering Department of the Massachusetts Institute of Technology. Several five ton electric trucks were carefully watched by them over a year and results recorded in their report dated October 1912. The insurance and current prices are New York city rates

COST OF TRUCK COMPLETE WITH $300 BODY—$4 000

Interest @ 6%	$240 00
Depreciation @ 10%	400 00
Insurance (all four kinds)	371 00
Garage @ $20 a month	240 00
Driver @ $18 a week	936 00
Helper @ $12 a week	624 00
Sundries	260 00
Fixed charges per year	$3 071 00
Fixed charges per day (1/300 year)	10 23

	Per Mile
Tires	$0 978
Current @ 4c K W H 40 K W H necessary for one charge for 30 miles	0 0533
Battery renewals	0 0528
Repairs, overhaul and painting	0 0378
Lubrication	0 013
Operating cost per mile	$0 2547

There is a great scarcity of data available for others than those in the electric vehicle manufacturing business showing what it costs to operate such machines, as it is generally assumed that the electric truck costs much less than does the gasoline truck. The electric vehicle manufacturers seem to be willing to let the matter stand as it now is, and we are doing our best to get the true figures, so more accurate comparisons can be made

ROBERT C. REID,
Harrolds Motor Car Company

"Comparing the Incomparable"

To the Editor of the SCIENTIFIC AMERICAN

I have been interested deeply in the articles upon motor trucking which ap-

pears in your issue of January 18th last. The pictures given on the front cover and on page 70 of this issue to accompany the articles by Messrs. Perry and Ritchie bring out in unique manner some of the comparative properties of motor trucks and horse-drawn wagons. But I do not believe the two comparisons are as discrepant as suggested in your editorial entitled "Comparing the Incomparable," and I desire to take this opportunity of pointing out wherein the view points of the articles differ

The article by Mr Perry considers only the 'possible" work by gasoline motors and by horse wagons. The daily mileage cited for horse wagons (16 to 20) is approximately what they are to-day travel ing in city services, the mileage of 40 to 60 per day as mentioned for motor trucks is being covered by those motors which are in comparatively long haul services, but is impossible by even high speed cars in a great portion of urban work. The services in which motors cover more than say 30 miles per day are admittedly too severe for horses, and most of them were not performed by road vehicles before the advent of the automobile A comparison of the cost of moving a ton over a mile under the two sets of circumstances is not logical, any more than it is logical to claim a superiority for the railroad which hauls between Chicago and New York at a lower ton mile operating cost than the road which hauls between New Haven and New York.

Instead of stating the possible performance of motor and horse wagons in entirely different services, it would seem desirable to consider their relative performances when used in the same service and under the same conditions. This was the basis of the data reported in Mr Ritchie's article As stated in the text particular services were selected for each size of wagon and the territory covered in each case was assumed to be within four miles of the loading points The results of comparing the horse, electric and gasoline wagons show that in this limited area the horse wagon is by no means out classed, particularly in the lighter capacities.

The reason for this deduction, which is referred to in your editorial as 'startling' is not hard to find It is the amount of standing time required by our present delivery methods, as horses are seldom moving more than 40 per cent of the working day The chief superiority of the motor truck over the horse wagon is the higher speed which is from two to three times that of the horse Thus, when the time taken in loading and discharging restricts the moving time of a motor to between 2 and 3½ hours per day the motor cannot travel any 60-mile distances. Particularly in retail deliveries is it difficult to reduce the standing time of a vehicle beyond certain limits as a large portion of this item is dependent upon the customer's convenience

Comparing motors and horses in this way is undoubtedly, as you suggest, like comparing a marathon runner with sprinters over a hundred yard dash ' But because the marathoner was defeated in such a match, who would claim that he was not well developed physically? Both he and the sprinter have their recognized places on the lists of a meet.

Just so with the horse, electric and gasoline wagons. A comparison of the three types of vehicles in a given service and under the same operating conditions shows one of the three to be superior In another service one of the other types might be superior, analysis only can tell. For the services cited in the report of the study by the Massachusetts Institute of Technology the electric truck was found to have advantages in point of cost. The Institute's study is intended to supply information by which the cost of performing a given service with each of the three types of vehicles can be compared. It is manifestly impossible to cover all classes of service in a single comparison.

Very respectfully yours,
H F Thomson, Research Associate,
Massachusetts Institute of Technology.

Painting the Wonders Under the Sea

(Concluded from page 178.)

resemble nothing so much as huge butterflies on the wing. Exquisite little fish noted for their curiosity of this strange creature in their world, and also for their almost unbelievably perfect and brilliant markings, crowd around him and swim between his fingers. The parrot fish are more dangerous, for their beaks, like those of our parrots, are sharp and strong, and if the fish is one of the larger species it can easily take a nip out of one's hand.

Under the water, says Mr. Pritchard, one seems to see rivers, lakes and water falls just as one does above the water. The gleaming sand, swept down by the action of the tides, furnishes this illusion. One of Mr. Pritchard's paintings of coral rocks gives the impression of a raging torrent, forcing its way between cliffs and dashing its spray up the sides of the rocks.

From sharks, octopi and swordfish there is, of course, danger. But Mr. Pritchard takes care never to descend in a spot where there is a notable absence of small fish, for that is a sure sign of danger. The most beautiful and bewildering sight of all, says the artist, is a school of fish darting by in a maze of reflected light, making the water quiver and scintillate and thrilling the silent watcher.

Mr. Pritchard's finest work has been done at Tahiti, but he has secured excellent subjects off Santa Barbara. According to the artist the coloring beneath the ocean is all in the lowest keys, merging from deep indigo and purple into the lighter delicate tints of pale greens, grays and yellows. Every point, every sharp edge shimmers like silver in the upper regions. Rocks and cliffs in the dim light assume an appearance of inconceivable size. On land we see the foundations of every object, no matter how large or small its bulk, but when one looks down into the depths of the huge coral formations under water they seem to be resting upon deep blue air.

Although he can work at any reasonable depth, Mr. Pritchard prefers about thirty feet, for there the light is clearer and at its best. He can remain under water when wearing a diving helmet over half an hour with perfect comfort.

Recent Improvements in Machine Tools

(Concluded from page 180.)

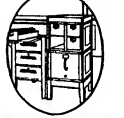
handles 11 permit the operator to slide the gears 5 into and out of mesh with the pinion 4 to start or stop.

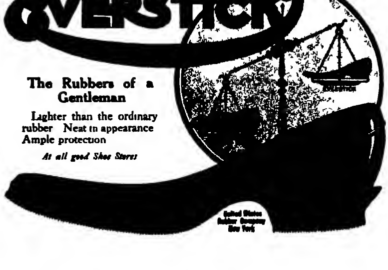
Each shaft 6 has two cranks, 12 and 21, the former, which operates the cutter, comprising a bolt 14 slidable in a T slot 11 in the shaft 6, positioned by the screw 16 and held by the sleeve 17, nut 10 and washer 18, the latter controlling the feed, consisting of the bolt 22 and sleeve crank pin 23 working in the slot 25 of the connecting rod 24. A screw 26 and block 27 limit the movement of the pin 23.

The connecting rod 30 connects the crank 12 with the cutter spindle 31, revolubly mounted in the knuckle 32, which is hinged to the adjusting turnbuckle 29 by the pin 33. The connecting rod 24 is adjustable as shown and connects the crank 21 with the feed connections. These consist of the bar 85, mounted to slide in the guide 86, and connected to the arm 87 of a bell-crank the arm 88 of which is connected by the rod 57 to the feed plate 56.

The cranks 12 and 21 are shown opposite for the sake of clearness, but are actually at an angle to each other.

The feeding mechanism is as follows. Projecting from the frame are the heads 37 with caps 38, in each of which is revoluble the outer eccentric sleeve 39, having a fixed gear collar 40. The last meshes with the idler gear 36 on the stud 63, and this meshes with the pinion 42 on the spool 43, mounted on the fixed shaft 41. A pinion 44 on the upper end of the spool 43 meshes with the gear 45 at the lower end of a sleeve 46, which is also revoluble in bearings 47 on the head 37.





The lower end of the driving sleeve 48 is revolubly supported in a depression in the upper end of the inner eccentric bushing 50, and is slidably connected to the spindle by the feather 49. At the upper end of the inner bushing is a ring 53 with oppositely extending ratchet teeth 54 and 55 which ring is secured to the flange 52. The feed plate 56, mounted just above the ring 53, has a pivoted block 58 connected to and reciprocated by the rod 57 and the crank 21, the stroke of this plate being determined by the screw 26. A plate 60 secured to the sleeve 48 by a screw 50, rides on the sleeve 40 and has a slot 61 containing the bolt 62, which engages the sleeve 46.

When the outer bushing 30 is turned, the gear 40 will turn the spool 43, and the sleeve 40 through the idler gear 36. The plate 60 thus acts as a crank of which the bolt 62 is the crank pin, so that the spindle will revolve at the same speed as the sleeve 40

The operation of cutting a square hole is shown in Figs 5, 6, and 7 A round hole is first drilled to admit the cutter 30 (Fig 5) which reciprocates up and down while being swung out to the position shown in Fig 6. The spindle 31 is then carried around a path 35 while it is turned in the opposite direction on its own axis, so that at the end of a proper number of strokes depending on the feed, the position shown in Fig 7 is reached

As will be seen the movement of the spindle is three-fold First, a lateral movement to get the required eccentricity—to carry its center to the path 35, second a movement in the path 35, and third, a reverse rotation on its own axis equal to the number of sides of the hole, divided by the number of sides of the cutter times a full revolution The last is caused by the turning of the outer bushing 30, and by means of the gears 40, 36, 42 44 and 45, the collars 40 and 48 and the plate 60 The second movement is also caused by the turning of the outer bushing 39 The first movement is caused by the turning of the inner bushing within the outer, and is accomplished as follows

A pin 64 carrying the spring held pawls 65 and 66, is mounted on the feed plate 56. The upper pawl engages the teeth 54 of the ring 53 so that as the plate reciprocates the inner bushing 50 will be turned. A stop 67 is secured to the ring 53 and a second stop 68 is mounted on the upper end of the outer bushing 30 When these two stops are in engagement, the spindle and outer bushing 30 will be concentric, the eccentricities of the two bushings being the same Turning the inner bushing within the outer will carry the spindle outward On the outer bushing is secured a worm gear 70, and around this worm gear is revoluble the ring 71 which has lugs 72 carrying the shaft 73, to which is secured the worm 74, which meshes with the worm gear The ring 71 carries a stop 75, which is in the path of the stop 67 Turning the shaft 73 of the worm 74 will position the stop 75 with reference to the stop 68, and thus limit the movement of the inner bushing within the outer As the feed plate reciprocates, the ring 53 and the inner bushing will turn, carrying the spindle outward until the stop 67 engages the stop 75 on the ring 71 As the ring 71 is locked to the outer bushing through the worm 74 and worm gear 70, any further turning of the inner bushing will cause the outer bushing to turn This results in first carrying the cutter from the position shown in Fig 5 to that in Fig. 6, and next, because of the common movement of both bushings, from the position in Fig. 6 to that in Fig. 7 At the same time, because of the gears 40, 36, 42, 44 and 45, the cutter turns back on its own axis one and one third of a revolution at each full revolution of the outer bushing.

To return the parts, the pawl 65 is disengaged when the eccentric bushing 50 can be readily turned back by hand until its stop 67 engages the stop 68 on the inner bushing.

The table 102 is constructed as shown so that the machine may be employed also as an ordinary slotting machine.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions books etc This will greatly facilitate answering your questions as in many cases they have to be referred to experts The full name and address should be given on every sheet No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request

(12749) W D A writes I take the liberty to make a correction in the answer to query No 12733 occurring in the issue of the SCIENTIFIC AMERICAN of January 25th in which F R asks why razors and other steel tools seem to lose their edge and when laid aside without sharpening seem to regain their original keenness. The theory regarding this is that the fine thin edge of steel forming the cutting edge of the tool is bent over in service and the tool becomes dull When we hone or strop this edge we bend it back into its original position and the tool is sharp once more If the tool is laid aside without honing or stropping this thin edge will gradually bend back of itself and the tool will be sharp again This is the phenomenon to which F R refers and is known as the elastic lag of steel It takes time however and is visible only under a fairly powerful microscope A We thank you for your suggestion of a different theory from the one we advanced regarding the belief that a razor can recover its edge by laying it away to rest. We have never met with any facts to show that a piece of steel or other metal in fact can bend itself back into shape after it has been bent beyond its limit of elasticity A razor edge or the edge of any other tool when turned over has been thus bent Elastic fatigue as it is usually designated does affect the time of recovery of a spring when not bent beyond its limit of elasticity But when this limit has been exceeded no force exists in a piece of metal to move it back again into its former shape We have never seen any references in scientific literature to support the theory which you advance and should be very thankful if you will give us the references to the authorities on this point upon which you base your statement We have many times examined the edges of razors under the microscope but never saw the recovery of the edge We are open to conviction and shall be glad to receive the references in question

(12750) F E V asks Will you kindly answer the following If a large tree located hundreds of miles from any living creature should be struck by lightning crash to the ground crushing many smaller trees in its downward path would it make any noise? The writer contends that although the sound waves would be set in motion there would be no sound unless they came in contact with an ear drum Is that correct? A Your query simply requires a definition of the word sound The dictionary gives two definitions One is a sensation the other is the physical definition which is used in all textbooks of physics and which is Such a rate of vibration as can affect the auditory nerve Sound the sensation cannot be produced excepting there is an auditory nerve to receive it and transmit it to the brain Sound the external cause of the sensation exists whether there is an auditory nerve in the vicinity or not Take your choice. Both definitions are correct There need be no controversy Most controversies would be soon settled if the parties determined the exact meaning of the terms employed in their discussions

(12751) R W asks A funnel shaped vessel 12 inches long 12 inches in diameter at the top and tapering to ¼ inch at the bottom is filled with water the top of the funnel being left open to the atmosphere The small end of the funnel is connected to a larger vessel in which the air has been extracted At what pressure would the water be discharged in the vacuum? A The case you send us is answered as follows The water will be discharged into the vacuum below with a pressure equal to the pressure of the atmosphere at the moment plus the weight of a column of water ¼ inch in diameter and 12 inches high The shape of the funnel does not affect the result Only the cylinder of water from the opening below to the top of the water is concerned in producing the pressure The principle is demonstrated in mechanics by what are called Pascal's Vases which are dishes of various shapes but all have the same sized bottom outlet and the same height or depth of water It is shown that the pressure in all at the bottom is the same. You will find these illustrated in almost any high school textbook of physics in your city library

(12752) C S asks B claims it is much easier for a person to swim in salt water meaning the ocean than in fresh water I claim the difference is too small to be noticed by the swimmer Will you please enlighten us on this subject? A It is much easier to float in salt water than in fresh water Hence it may be said to be easier to swim in salt water but a person must push his weight of water out of the way every time he moves his length in either case and thus the work done in swimming is the same in both salt water and fresh. Work is equal to the resistance times the distance the resistance is moved. In this case the resistance is the weight of water which is pushed out of the way by the swimmer Water equal to one half of the weight of the swimmer is pushed sidewise to a distance equal to one half the width of the swimmer on each side of the swimmer This gives the work done in swimming each time the swimmer moves his length.

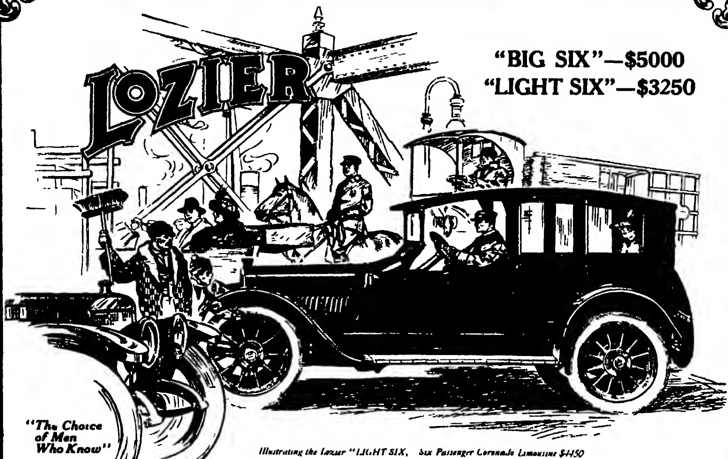
"BIG SIX"—$5000
"LIGHT SIX"—$3250



Illustrating the Lozier "LIGHT SIX," Six Passenger Coronado Limousine $4450

IN THIS, the sixth successful season of Lozier Sixes, even with Lozier production increased fourfold in its two great plants, there will not be enough Loziers to supply all those who want them. Every prediction made last fall has come true. Every forecast Lozier dealers made has worked out to the letter Therefore, those who expect to get their Loziers this year will do well to place their bona fide orders now, just as more than fifteen hundred purchasers have already done

To everyone who knows the automobile industry and the relative regard in which the several high-grade cars are held, there is nothing surprising about the sweeping success of Lozier this year

For eight years the Lozier has been the only American-built car that has commanded and still commands a price of $5000

For six years the Lozier has been the most talked-of six-cylinder car in the world

Up to the Fall of 1911 when, with the winning of the Vanderbilt Cup, Lozier withdrew from racing because it seemed that any further victories could add no higher honors and because the car had been brought to perfection by what racing had taught in years of grilling tests—up to that time every principal honor the American speedway could offer had come to Lozier

Year after year these victories came because the Lozier was built right A Lozier was never withdrawn from a race because of mechanical difficulties. Lozier strength, power, endurance and safety won these races, just as Lozier strength, power, endurance and safety have won the respect and admiration of all men who know motor cars.

And the Lozier continues to lead all American cars with no other builders sufficiently endowed with ideals and experience to combat its leadership

No wonder, then, that when the Lozier "LIGHT SIX a true Lozier for $3250 — was added to the line this year, thousands wanted this car Thousands who for years have wanted Loziers but did not feel they could afford to pay $5000 for one

No wonder that dealers all over the country telegraphed or came to Detroit to secure the Lozier agency No wonder that our branches in the principal cities received as many as fifty calls and letters in a single day asking them to arrange demonstrations

The Lozier "LIGHT SIX" has simply swept everything before it in the high grade field No other car commonly reputed to maintain similar high-grade standards of construction and service offers a Six at anywhere near the Lozier "LIGHT SIX" price at $3250

The Lozier "BIG SIX" will set a new record in the sale of $5000 cars—for men who know automobiles and can afford to take advantage of their knowledge are satisfied with nothing less than Lozier quality And Lozier quality in its entirety mechanical precision, power, luxury and comfort—is found only in Lozier cars

Lozier leadership was never so firmly established as it is today

LOZIER "LIGHT SIX"

Left side drive, center control—streamline body design, Electric Starting and Lighting System Touring and Runabout models $3250 Coupe $3850 Limousines $4450

LOZIER "BIG SIX"

Left side drive, center control—electric lighting Smokeless oiling system unequalled fuel economy Touring models and Roadster $5000 Limousines and Landaulets $6500

Catalogues mailed on request

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly the world's progress in scientific knowledge and industrial achievement.

The Naval Reserve Movement

THERE have been few movements of national importance that more vitally affect the interests of this country than the proposal to establish a sea-going naval reserve for the United States. The material for such a reserve is present in abundance. We have heard so much about the decline of our merchant marine, that we are apt to forget that this decline affects the deep-sea trade only, and that the scarcity of American sailors is confined to that branch of the shipping trade. Not many people realize that the tonnage of our coastwise and lake marine is greater than that of the whole merchant fleet of Germany, and that in all probability not far short of one hundred thousand men are required to man this tonnage. In the coastwise and lake trade then the Government can find a field for recruiting which contains material of the very best quality. We entirely agree with our contemporary, the *Marine Journal*, in its conviction that no better seamen can be found anywhere in the world in their several ratings than the masters, deck officers, engineers, oilers, water tenders, quartermasters, etc., of the large fleet of American steamers sailing from the port of New York and engaged in trade to our own eastern and southern ports, the Gulf of Mexico and the West Indies. From our coastwise shipping, then, it is possible to recruit for the naval reserve men who are skilled, reliable and possessed of that ardent patriotism which goes to the making of good navy sailormen. From the port of New York alone it should be possible to enroll several thousand men for the proposed naval reserve, who in the emergency of war might be assigned at once to the auxiliary ships which are necessary to a fighting fleet. Our navy could thus be strengthened at the very point where it has proved, and may yet prove, to be weakest in the stress of a long-drawn-out naval war. Similar recruiting could be done at Philadelphia, Baltimore, Norfolk, Boston, Portland, Puget Sound and San Francisco. This source of supply concerns only our coastwise trade. To this must be added the fruitful recruiting ground offered by the large body of qualified seamen to be found on the big steamers of the Great Lakes.

The proposal of the Government is to enroll the officers and men of the merchant service, give them the necessary amount of instruction and a reasonable compensation, and thus have at command a large force of trained men ready at the nation's call. We commend this movement to the hearty co-operation of every one who can assist in bringing it to a successful consummation. The naval reserve of Great Britain is large, efficient and full of enthusiasm. The service is extremely popular. Officers and men alike are proud of the distinction of wearing the naval badge, and of the fact that their ships fly the blue flag of the Royal Naval Reserve. There is no reason to doubt that a similar popularity would follow the establishment of a naval reserve for the United States Navy.

Morse Signals from London to New York

THE announcement recently made that Morse telegraph signals were being transmitted direct between London and New York over the lines of a cable company indicates that the chief problem of cable electricians for many years and the goal of endless experimentation and research has perhaps been attained. Furthermore, it is most appropriate that the engineer to whom this accomplishment is due, is one whose life has been spent in the development of submarine telegraphy, and that this successful outcome of a long series of experiments and practical tests forms a fitting climax to a notable career.

Those familiar with manuals of electrical testing will recall such methods as the electro-static capacity measurement of a submarine cable and the condenser method for determining its resistance associated with the name of John Gott, and it is to this distinguished British engineer that we now owe this most recent development which promises to revolutionize submarine telegraphy and make still more difficult its replacement by wireless. Mr. Gott, now well along in years, is the senior consulting engineer and chief electrician of an important cable company, over whose lines the new method has been used for several months with entire satisfaction to the engineering and operating staff of the company. Beyond the announcement of the success of the new invention and the securing of the rights for its use, no statement of technical or other details has been made, but we are authoritatively informed that the method has been used successfully over the long, or transatlantic, section of the cable for several months, and that the complete line between London and New York has been worked direct. Morse signals, sent by hand as fast as a skilled operator could put them on the wire, have been clearly transmitted, and while automatic transmission at high speed has not as yet been attempted, it is undoubtedly a possibility of the future.

Hitherto the limiting distance for the transmission of Morse or dot and dash signals through a submarine cable has remained at about 500 miles, and in practical long distance cable working use is made of a sensitive galvanometer, or rather some modification such as the siphon recorder, to indicate the flow of the current in the cable corresponding to the signals. Obviously to reproduce the range of the overland telegraph and the ease with which relays and repeating devices could be utilized to link up circuits of practically unlimited length was no mean task for an inventor, and many a cable electrician has carried on refined and indefatigable researches in this field. But submarine cable working at best is complicated by many considerations that do not apply to land lines, and the use of repeating devices is attended by difficulties realized by few outside of those electricians specially skilled in this department. Therefore Mr. Gott's discovery is little short of epoch making, and the details of the method and instruments, which we hope shortly to describe, will be awaited with great interest by all. Not only is the future of submarine telegraphy concerned, but also that of radio-telegraphic communication across the oceans. Will it be able to compete with more efficiently operated cables any more than it does with our present land lines?

The Passing of a Great Ironmaster

WITH the death of John Fritz, America has lost a pioneer ironmaster and one of the most distinguished manufacturers in that iron and steel industry in which this country leads the world. John Fritz died at his home in Bethlehem, Pa., on February 13th, at the age of 91, and he has left behind him a name and a record which in that broad field of engineering in which the activities of his busy and fruitful life was spent, are as honorably known abroad as they are in his native country.

In many ways John Fritz was the typical successful American inventor. Like many before him whose fame has gone abroad in the land, he started life in comparatively obscure surroundings and without any of the great advantages of education and financial competence which have given many of the later inventors and engineers a flying start in the race for successful achievement and honorable recognition.

John Fritz's father was German, his mother Scotch, and he was born in Chester County as far back as 1822. He picked up his practical education while working on a farm and later, as an apprentice in a blacksmith's shop, his apprenticeship dating from the year 1838. From the first he had a taste for mechanical work, and his biographers speak of his invention of an improved shotgun which was so efficient that the men of the neighborhood came to the young man eager to have his improvement applied to their guns. In 1844 Fritz went as apprentice to a mill for rolling bar iron which had been built at Coatesville, Pa., and there his ability so quickly asserted itself that in six months' time he was in charge of the plant as ironmaster. At once he began to introduce improvements into the puddling, heating and rolling of bar iron, with the result that in 1854 he was asked to assist in building the well known Cambria Iron Works at Johnstown, Pa.

Even at that early day the distrust by the workmen of labor-saving devices showed itself and the imported Welsh puddlers and rolling-mill men fought young Fritz at every turn. He lost his mill by fire and with it went practically all of his capital. Undaunted, he sought and obtained fresh financial backing, and came back and rebuilt his mill on a larger and more improved plan. Federal recognition of Fritz's genius came during the civil war, and the Government engaged him for the mill which it had established at Chattanooga, Tennessee. Here he manufactured rails and repaired locomotives for the Government.

When the Bessemer method for the production of cheap steel was introduced into this country, Fritz at once realized the enormous value of the process. Fritz, Holley, and Jones at once applied their genius to the improvement of the process, and it was they who laid the foundation of the enormous industries which are now represented by the iron and steel trade in this country.

It is well understood that the re-creation of our Navy was rendered possible only when our ironmasters agreed to take up the manufacture of armor plate and the necessary forging for guns of heavy caliber. In this movement, John Fritz stood foremost, and to him we owe the adoption of the Whitworth processes from England and the French processes of Schneider-Creusot; indeed his Bethlehem plant was the first to take up the manufacture of armor plates in the United States.

Lehigh University owes much to the trusteeship and generous assistance of Mr. Fritz, and Columbia University in 1898 conferred upon him the degree of Master of Arts. He was an honorary member of the American Society of Civil Engineers, was president of the American Society of Mechanical Engineers and also of the American Institute of Mining Engineers. In 1893 he was awarded the Bessemer gold medal by the unanimous vote of the Iron and Steel Institute of England. Furthermore, he was elected an honorary member of that society, at which time there were but five other names carrying that rare distinction. Among these were the Prince of Wales, King Edward of England, and the late Abram Hewitt of New York. On Mr. Fritz's eightieth birthday was founded the John Fritz Gold Medal for achievement in engineering sciences in this country. John Fritz was not more distinguished than he was beloved. The writer well remembers the occasion of the presentation of the Fritz medal to Sir William White, formerly chief constructor of the British navy, and the entrance of the venerable Fritz, rather late in the evening, when the whole audience of distinguished American engineers rose to its feet in loving and reverential tribute to the aged ironmaster.

Indexes in Scientific Books

IT is high time somebody voiced the sentiments of the world at large with regard to the almost universal custom among French scientific writers of publishing indexless books. Few things are more exasperating than a reference-book without an index—unless the contents of the book are self-indexing in virtue of an alphabetical arrangement or otherwise—and most treatises, in good standing, on scientific subjects serve more or less as reference books. German and English scientific books are almost always indexed, French almost never. The omission of the index is simply a piece of unmitigated laziness on the part of the author, who deserves to be castigated accordingly. It is unfortunately true that ideal indexes are rare in every language. Some one has expressed the importance of a good index by saying that an author should always make his own index, even if he lets somebody else write his book—and this is hardly an exaggeration. The present writer, who happens to take a particular interest in meteorology, has in mind several cases in the literature of that science in which the indexes are so badly made that it is usually easier to hunt down a topic in the text than to seek it by way of the index. Davis's "Elementary Meteorology," an otherwise admirable treatise, furnishes a shining example of the kind of indexing that ought to be avoided. After an entry in the index one finds references to a dozen different places in the text, including all the unimportant allusions to the topic in question, as well as the places where it is seriously discussed. It would have been so easy to put the important references in full face type or italics! On the other hand, the greatest of all works on climatology, Hann's "Handbuch," is very meagerly indexed. This work is rich in the local nomenclature of climate, but one seeks in vain to run down through the index the places in which the author mentions such interesting phenomena as the "pontias," the "Wisperwind," the "calina," and so on. The only large work in any language on atmospheric optics, Pernter and Exner's "Meteorologische Optik," contains no index, and few books stand in greater need of one. However, this case is a striking exception in the German literature of meteorology, whereas in the French literature of the subject one hails with delight the rare case in which a book contains a "table alphabétique" as well as a table des matières." Doubtless the botanist and the zoologist, the astronomer and the physicist, will eagerly join their meteorological *confrère* in an appeal to French scientific writers for more indexes.

If, besides indexing their books, the French should take to spelling English and German names correctly, then truly the millennium would be at hand.

Engineering

Sanitation at Panama.—Coming after the statement in the press that the mosquito has begun to develop again in great numbers in the Canal Zone, the last report of Col. Gorgas, chief sanitary officer of the Canal Zone, is timely. The tables show that the year 1912 was the most satisfactory of any since work started in 1904. For the month of December the average death rate per thousand among employees was only 7.14 as against 10.42 in 1911, 25.3 in 1908, and 45.73 in 1905.

Block Signals Compulsory.—In its final report to the Interstate Commerce Commission, the Block Signal and Train Control Board made the important recommendation that all interstate railroads should be compelled to adopt the block-signal system. The Board also recommended that tracks be inclosed and laws against trespassing be enforced. From eight to ten thousand people are killed in one way or another on our railroads every year, and a very large portion of these accidents are due to trespassing on the tracks.

Extensive Railroad Construction in the Northwest.—During the ten months which ended October 31st last, a total of 698 miles of railroad was constructed in Alberta, Canada. The *Engineer* draws attention to the fact that, since 1909, there has been an activity in railroad construction in Alberta without precedent in the history of the North American continent. In 1912, the Canadian Northern Railway built 463 miles of new line and the Grand Trunk Pacific increased its mileage from 384 to 619 miles.

The Three-million-yard Slide at Culebra.—Another huge slide, the largest that has yet taken place, has commenced at Culebra. The present indications are that about 3,000,000 cubic yards are in motion, and that it will take until the late autumn to remove the material. By that time the water will be in the cut, and the two big dredges, now building, will be on their way to the Isthmus. These dredges, which have a combined capacity of over one million cubic yards per month, should easily keep the cut open when once the water has been turned in.

Launching of the "Aquatania."—The launching of the "Aquatania" of the Cunard Line is set for Tuesday, April 22nd. This vessel is 900 feet long and she will exceed 50,000 tons gross in tonnage. In everything except speed, she will be an enlarged "Mauretania." Her probable speed will be 23 knots. She has been constructed with the same system of longitudinal bulkheads that characterizes the "Mauretania" and "Lusitania," and she has a watertight lower deck, extending throughout her whole length. Her stern frame and brackets weigh 130 tons with the other parts in proportion. The total number of persons she will be capable of carrying is about 4,500.

New Freight Terminal at Long Island City.—A new freight terminal costing $1,000,000 has been planned for Long Island City which will give manufacturing concerns in that locality close connections with the railroad systems of the country. The property on which the terminal and piers will be located covers several city blocks, and the plans include a huge freight yard with a capacity of about one thousand freight cars. The docks will accommodate the largest ocean-going freighters, and slips will be provided for the largest car floats that are used in this harbor. A belt-line railroad will connect the entire Queens district business section with the terminal.

Provision of Life-boats.—The British Board of Trade has just issued the revised rules for life-saving appliances at sea. A table showing the number of davits which must be provided specifies what number must be carried on vessels of various lengths. Thus, vessels under 160 feet in length must carry two davits. Vessels between 245 and 270 feet must carry six davits. Those of from 360 to 390 feet, ten davits, vessels of from 450 to 510 feet, fourteen davits. Those from 590 to 670 feet must carry eighteen davits, etc.; those from 750 to 840 feet, twenty-two davits, and vessels from 940 to 1,040 feet must carry twenty-six davits. The number of life-boats, or approved substitutes therefor, must provide a seat for every passenger. Motor life-boats may be fitted, but their use is not encouraged.

Electrifying the Panama Railroad.—Now that the relocation and reconstruction of the Panama Railroad is completed, surveys are being made for the transmission of power for the electrical operation of the road. Under normal conditions power will be taken from the Gatun hydro-electric plant, which is now under construction, but there will also be a connection with the present steam electric plant at Miraflores. Current will be transmitted at a pressure of 44,000 volts, and at the various points of distribution it will be reduced to the desired voltage for running the trains, for lighting the canal, and for operating the various machine shops and the gates and other appliances at the dams and locks. The railroad tracks will be spanned by the usual bridges for carrying the cables, etc., which will be placed at distances of from 200 to 300 feet, according to the local curvature conditions of the railroad.

Electricity

Novel Use for an Electric Flatiron.—A recent English electrical paper reports that an ordinary electric flatiron was called into playing a new rôle by the resourcefulness of an automobile driver. Being obliged to leave his car in an unheated garage over night, with the radiator and the cooling system of the car full of water during a spell of cold weather, the driver connected the electric flatiron to the lighting circuit and placed it under the car bonnet, where it served to protect the engine from probable destruction from freezing of the water.

Lowering of Resistance by Extremely Low Temperatures.—Recently reported experiments of a Dutch investigator have gone far to confirm the theory that the electrical resistance of all conductors would be reduced to zero by cooling the conductors to the absolute zero of temperature. By boiling liquid helium in a partial vacuum a temperature of only three degrees above the absolute zero was attained. At this temperature the resistance of mercury was found to be only one ten millionth as great as at zero Centigrade.

From Oil Lamps to Electric Lights at a Bound.—Thanks to a proposed harnessing of a small water-power in Yorkshire, England, the people in certain sections of that county seem destined to pass from the primitive candle and oil-lamp epoch direct to the electric light, in an evolution of illuminating methods skipping the use of gas altogether. Gas has never been provided in this section, but now a hydro-electric corporation composed of villagers, including the postmaster and schoolmaster, proposes to utilize the power of a small stream or "beck" to generate electrical energy and sell it at a charge of six-pence per unit.

Uninsulated Aluminium Windings on Electrical Machinery.—In the manufacture of electrical machinery the dissipation of the heat generated in steel coils and armature windings has been improved by using bare aluminium conductors without any other insulation than the film of oxide which forms on the surface of this metal. It has been known that coils wound with conductors of square cross-section cool down about 40 per cent better than coils wound with round wire, because with the round wires the air spaces between the consecutive turns and layers in the windings operate to check the flow of heat. The film-insulated aluminium conductors carry the benefits of using conductors of square cross-section a step further by getting rid of the cotton or asbestos insulation which is ordinarily used. The superior heat-dissipating qualities of these aluminium windings show to special advantage in the construction of lifting magnets which use heavy currents and are frequently called upon to lift hot castings, etc. In lifting magnets electric car motors, and many other devices the saving of weight is also an important item.

Sewage Purification by Electricity.—Electrolysis as an aid to sewage purification is a rather recent development and much more is to be expected from it. Oklahoma City has installed a plant where this treatment is successfully applied. A slow stream of city sewage is run through flumes between batteries of iron electrodes. A current of 270 amperes and 2.5 volts is passing between the electrodes and of course produces considerable electrolysis of the salts contained in sewage. The result of such electrolysis is to liberate a great deal of oxygen and some ozone at the anodes. This active oxygen and ozone oxidizes the organic matter into harmless and unobjectionable products. At the cathode some metallic hydroxides or bases are formed and these assist in coagulating the floating filth. Colloidal particles in fine suspension are also driven to the electrodes and collected in masses large enough to settle. This Oklahoma plant has a capacity of 750,000 gallons every twenty-four hours at a cost of operation of only $2.16. The municipality is now building a plant for the electrolytic formation of a flocculent precipitate, capable of treating 4,000,000 gallons daily.

The Talking and Moving-picture Machine.—On Monday of last week the Edison kinetophone was exhibited for the first time in public on the stages of four prominent vaudeville theaters in New York city. In the first film a man made a speech explaining the perfecting of the talking picture by Edison in the obtaining of absolute synchronism between the picture and the sounds. Then a pianist played, a bugler sounded the reveille, a young lady sang, and some dogs appeared and barked. The dogs gave the most striking and natural demonstration of the new apparatus. A second picture showed a minstrel show in which the various members of the troupe performed as naturally as in real life, though there was no mistaking the fact that the talk and music were produced by a phonograph. The intensification of the sound necessary in a theater apparently gives to it more of that metallic quality of which it has been successfully deprived in the smaller drawing-room machines. Nevertheless it is no more disagreeable than the voices of many of the actors who appear on the vaudeville stage. The present talking pictures last about five minutes each, though we understand a French machine has been perfected in which each film runs three times as long.

Science

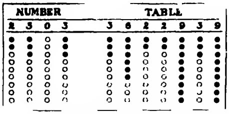
Restoring Elasticity to Caoutchouc.—Caoutchouc, which has a tendency to grow hard from exposure to the air, may have its elasticity restored, according to *La Revue*, by merely dipping it in a 3 per cent solution of aniline. To preserve the red or black tint which has a tendency to turn gray, a 1 per cent solution of penta-sulphate of potash is employed. This process, however, involves the disengagement of an offensive odor, but restores the elasticity admirably. Equally good results are said to be obtained with a mixture of glycerine and water, but this unluckily injures the look of newness.

International School Hygiene Congress.—The Fourth International Congress on School Hygiene will be held at Buffalo, N. Y., August 25th to 30th, 1913. The three previous congresses have been held in 1904 at Nuremberg, in 1907 at London and in 1910 at Paris. The object of the Congress is to advance the health of school children and while it will include in its display a scientific exhibit representative of the most notable achievements in school hygiene, it should also offer an opportunity for the exploitation of improved ideas and devices, whether patented or not, along the line of the Congress.

Chlorophyl and Ultra-violet Rays.—A report on the action of ultra-violet rays on chlorophyl has been made to the French Academy of Sciences. MM. C. Dhéré and W. de Rogowski, who have been investigating the subject, find that the pure chlorophyls present a marked relative transparence to the rays of the extreme ultra-violet portion of the spectrum. The natural chlorophyls, in solution in ether, show only a single band of absorption exclusively ultra-violet. This common band is situated in the middle region of the ultra-violet spectrum. This furnishes yet another proof of the biologic importance of ultra-violet rays as affecting vegetation.

Stereopticon Views in Natural Colors.—Following the giving of popular magic lantern shows in natural colors in Paris last summer which was made possible by the autochrome process of Lumière, Miss Elizabeth Marbury has introduced into this country similar lantern slides for the purpose of giving "Color Conferences" in which various famous places, paintings and the like are shown as they really appear. M. André de Fouquières lectures in his native tongue for such as understand his language, and other well-known American artists and lecturers describe the pictures for the benefit of American audiences. M. de Fouquières has lectured on Persia and Versailles, while Mr. Christian Brinton has described Spain, the Alhambra, and the wonderful paintings of Velasquez, Murillo, Titian, Rubens, Van Dyck and Goya in the Prado at Madrid. The process used in these pictures recently shown in New York is the Gervais-Courtellemont. It is similar in principle to the Lumière process heretofore described in our columns, the only difference being that in place of colored starch grains used as a screen on every plate microscopic colored bars are employed. On account of the density of the slides caused by this screen a very powerful 45-ampere arc light is required to project them and the heat is so intense that there is great danger of cracking if the slide is left in the lantern more than half a minute. The results obtained are very beautiful whether it be in reproducing paintings and tapestries or scenes from nature such as flowers, sunsets, and autumn foliage.

A New Hygiene for Gastric Troubles.—Recent cable dispatches from Paris have announced a novel method of treatment for stomach troubles, consisting in exercise taken by the patient while in the position known as "on all fours." Naturally this has aroused more or less derisive comment on the part of the non-scientific but ready-tongued journalists of the day, who have looked upon it as merely another instance in the long list of health fads and fake cures. That it is something more than this is proved by its serious presentation in such a journal as *La Gazette Medicale*, of Paris. The author of the treatment, Dr. Meunier, advises it, not as a panacea, but to remedy a specific condition, namely, the slow or imperfect evacuation of the gastric contents of the stomach, which is as is well known one of the most frequent functional troubles in the pathology of the stomach. Among the causes of this is what is known as the "stomachic ptosis," i. e., the stagnation of the mass of food contained in the pouch of the stomach. Dr. Meunier proved by a series of chemical experiments and X-ray photographs of several patients that evacuation of the stomach proceeded with much greater rapidity in this position than in the normal attitudes. The explanation of this is sought in the assumption that in the evolution of mankind a change has been made from the horizontal to the erect position of the body. The stomach has remained still imperfectly adapted to the new attitude and therefore functions better in that common to our four-footed ancestors before the intricate development of brain and hand led them to stand on two legs so that they might use their hands freely for offensive, defensive and industrial purposes, as well as gain the advantage of increased height and a greater range of vision.

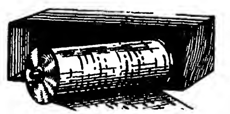


One of the original cards that Babbage used in his "calculating engine"—an invention which was never completed, but which was full of promise

Keeping Books by Machine

The Punched Card as a Saver of Brain Energy

By H S McCormack



By means of electrical contacts made through holes in thin sheets of brass, the most complicated selections can be artistically rendered upon the piano.

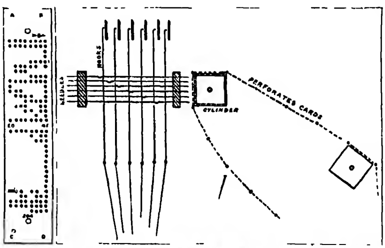
The facts embodied in this article warrant the predictions made by the author and are worthy of serious consideration Mr McCormack foresaw present needs by inventing years ago the original typewriter tabulator He has studied advocated and applied efficiency by originating and introducing mechanical inventions into accounting and billing and has proved that his insight into these intricate matters has been based not upon theories but fact The SCIENTIFIC AMERICAN *has arranged for several articles from this author, a recognized authority on efficiency as applied to office and executive management* EDITOR.

ABOUT a half century ago an English man named Babbage started work on an invention which is only now nearing completion He had studied the operation of the Jacquard loom which through the medium of punched cards weaves designs in fabrics Holes are punched in the cards to form any design required—no matter how ornate—and the card in turn causes the loom to produce the pattern in many varieties of textiles

Babbage figured that if punched cards could build designs in textiles there was no reason why they could not be utilized in the same way to make records.

With this idea in mind he built a device which he described as a 'calculating engine." He induced Parliament to appropriate £25,000 to further his invention Unfortunately this money was speedily used up in experimental work and Babbage got no further than a crude hand made and incomplete model of a device he had in mind Parliament was skeptical and refused to advance more funds, so Babbage was obliged to cease work and the invention was lost to England

Since Babbage's day the Jacquard principle has been successfully applied to musical instruments, and rolls of punched sheets operate pneumatically the keys of a piano or organ. More recently through the medium of thin sheets of brass in rolls an electrical contact is made through the holes, and the most difficult compositions are rendered upon the piano with the crescendo effects and tempo changes of an accomplished musician



The Jacquard loom through the medium of punched cards, weaves designs in fabrics. Holes are punched in the cards to form any design required, no matter how ornate, and the card in turn causes the loom to produce the pattern in many varieties of textiles.

How Our Population is Counted and Tabulated With Punched Cards.

Not many years ago the punched card principle was first applied to statistical work in the United States. Its most prominent use has been in its application to census work In fact it has always been called the census machine" Formerly the tabulation of population by States, cities towns and hamlets the segregation of the classes by native and foreign born male and female white and black, etc, was performed tediously by hundreds of clerks, with the usual percentage of errors and with little opportunity for securing automatic checks such as are to-day so vital in correct analysis. In addition it took about ten years to complete the work Now it takes ten months.

After the Government found this machine so successful in its work, it was adapted to cost accounting and has been used extensively by large firms Inventors of business appliances began to see that the punched card principle was capable of infinite adaptation and could perform operations which were previously considered impossible for a mechanical agency to execute

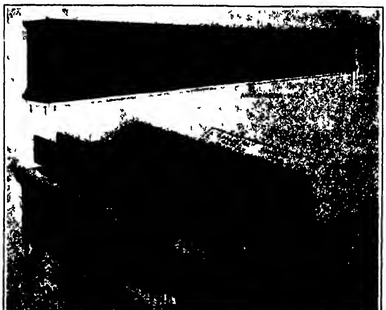
An interesting example is the automatic typewriter which actually takes the place of the human fingers for making duplicate letters

The Player-piano Principle Applied to the Typewriter

The writer a few years ago journeyed to Detroit, Mich, and inspected a hand made model of an automatic typewriter operator Here was employed the same principle—punched holes in rolls of paper—to turn out form letters actually typewritten At the time of the examination the hand made model was a very crude affair of the 'soap box' variety but the principle embodied in the model made it a commercial possibility One of the leading manufacturers has taken the device under his control, and developed it to a point of practical usefulness. It is almost impossible to recognize the finished product as an evolution of the crude hand made model produced by the inventors. The device to-day is supplied with a quantity of letterheads and the electrical current turned on through the application of the pneumatic principle the machine automatically picks up a letterhead and places it in the carriage of the typewriter The letter is spaced forward to the date line and the typewriter begins to operate as though actually under the impulse of human hands and fingers. The typewriter carriage moves to the right and the name, address and salutation are properly placed on the left of the letterhead.

Moving from space to space—the keys being depressed and the type bars flying up and down—there is something almost uncanny in the operation of the typewriter as it proceeds step by step to turn out a complete typewritten letter The completed letter is removed automatically, with no human hands near, and another letter is started. The name address and salutation are automatically changed and the operation repeated, letter after letter, until the machine automatically stops. Approximately four hundred duplicate business letters a day can be typewritten by this machine

The automatic typewriter takes the place of human fingers. It uses a punched roll of paper like a player-piano. By the application of the pneumatic principle the mechanism operates as though actually under the impulse of human hands and fingers.



Some day we will have a ledger cabinet, showing debit and credit dials, operated by cards. Clerks will be supplied with cards already punched with their own number, also the number of their department. When a sale is made they will punch and not write the amount as they do now.

Now comes what seems the most wonderful application of the punched card principle—that of mechanical bookkeeping and business recording—almost replacing the human brain in its performance, and indeed out distancing it in accuracy. Through a prearranged plan, four business men recently met: one a railroad official from a distant city, another an official connected with one of the country's leading industrial corporations, the third an official of the greatest textile company, while the fourth was the president of a concern of international reputation.

These men were brought together for the purpose of considering at a private demonstration a mechanical marvel which was the result of years of study, hardship and ingenuity on the part of an inventor assisted by mechanical experts whose experience qualified them to carry out the plans of the inventor. The result of years of painstaking effort, trials and disappointments, costly experiments and the expenditure of thousands of dollars could all be shown in a few moments. A few minutes demonstration does not, in this particular case, mean that these men, who were authorities in their fields, understood all they saw. What they beheld in actual operation was almost incredible. Although they were prepared in advance to see certain results accomplished, they could not grasp in less than an hour the details of a principle that will radically affect methods of mechanical accounting.

When these men met at the appointed hour and place, a waiting taxicab whirled them to a section of the west side of New York, which was totally unfamiliar to them. Arriving before a large loft building, the guide led the little party to a machine which accomplished what was heretofore possible only by human intelligence.

That machine performed the remarkable feat of recording approximately eleven entries of a single transaction—eleven entries which would ordinarily have to be made with a pen with eleven chances of making a mistake. In recording a sale the amount is entered upon a sales check, to be entered upon a bill, again upon the segregated sales record, again into the sales ledger, through another operation placed to the credit of the sales person, then to some department, in addition to a record as to whether the package was delivered by mail, carried away or sent by regular delivery or express. Instead of this constant juggling with the same figures through a maze of operations there will be an original entry upon a punched card and this card will, through the medium of motor driven machines, be automatically sorted into various divisions and subdivisions, and recorded item by item upon counters or wheel sets into adding mechanisms.

Prediction of the Mechanical Ledger

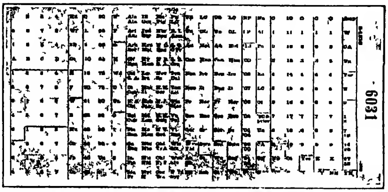
The ledger cards for the A and B ledger will be placed into a machine, the current will be turned on and with the sales checks in the magazine the machine will pick out the ledger card of Adam Aaron and from the magazine pick out the sales check of Mrs. Aaron and will debit the account with 13.73, and at the same time add the amount into the total register. After the ledger postings are complete, the sales checks will be passed through the machine again and listed according to departments. When the department totals are secured, the sales checks will be sorted and listed according to sales persons. At the completion of each sorting, the machine will automatically throw a lever and start the printing mechanism, which will deliver to the operator a printed adding machine list showing the items according to the desired segregations.

As the checks are received in payment or part payment of accounts, the entry will be punched upon a card, the ledger sheets will again be returned to the machine, and in red upon the ledger sheets will be printed the credits. Automatically the amount paid on account will be subtracted from the debit, and the balance, or amount remaining unpaid, will also be printed upon the ledger sheet.

The same principle will be applied to pay rolls, in other words, the laborious accounting of to-day, the repeated juggling of the same figures into the various combinations necessary to analyze a business scientifically, is to become a thing of the past.

If firms could eliminate half of the expense in their accounting departments, losses would be turned into profits and companies who have never paid a dividend, and those who have failed to pay ordinary dividends, would immediately be classed among the successful dividend-earning companies.

An understanding of the principles described will convey to the reader something of what these four men saw in operation. They saw entries of sales placed upon cards half the size of an ordinary playing-card. They saw when the entries were typed that under-



By means of such cards the United States Census Bureau tabulates the population by States, cities, towns and hamlets. The work, once performed in years by hundreds of clerks, with many errors, is now performed in ten months.

neath the figures were small round holes. The number of the department, customer's number, clerk's number, amount of sale, and other details according to requirements, were entered upon these small cards. A thousand cards were placed into the magazine of the machine and the current turned on. The machine itself was one hundred adding machines worked into an integral whole. A part of the mechanism was one hun-

A machine in use by the Census Bureau.

dred wheel sets, upon which were being accumulated these various amounts. If the machine picked up a card for Department 12, whatever amount had been punched upon this card was properly recorded upon wheel set 12.

When the machine finished sorting all the cards a lever was thrown, and automatically a printed strip appeared which was identical in appearance with the printed strip secured from a listing adding machine. The printed strip gave the results of departments 1, 2, 3, etc., up to 100, and opposite each department was set down the amount sold. Then, as a grand *finale*, the machinery clicked, a number of levers arose and there was printed one grand total showing all amounts which had been segregated to the various departments, all grouped into one grand total.

A Further Application of the Jacquard Principle

There is possible a still further application of the Jacquard principle and inventors will no doubt get to work to apply the same principle to addressing machines. An ordinary card index will be used. The name of John Jones, 261 Broadway, New York City, will be written upon a 3 by 5 card, while underneath the name and address will appear numerous perforations. The cards will be very inexpensive and can be utilized for follow up or for regular customers, pay roll, etc., and no expensive machinery will be needed to make up new stencils.

There is nothing but common sense in all this. To illustrate: Some four thousand years ago, a method of laying bricks came into practice, and this same method was handed down from generation to generation until very recently. Now, a disciple of Frederick Taylor—Gilbreth—has changed the general order of things and reduced the number of wasteful operations until to-day a bricklayer with less effort can lay double the number of bricks. Gilbreth did not discover any new principle. He simply applied common sense to a well known principle and applied it to mortar and bricks instead of tools and steel.

In almost every business house in the country some parallel case can be brought to light by an efficiency engineer when making his examination.

It is common to find a business firm applying efficiency to the order, requisition and billing while totally ignoring the same principles which could be applied to their voucher system with equal results in saving of time and expense. On the other hand, a department store with appliances and systems of various kinds will retain in its purchasing department an antiquated method for requisitions simply through failing to see that the same ideas used so effectively in other directions are really a principle which, when combined with a little common sense, go far toward reducing friction and promoting efficiency.

The Pneumatic Typewriter

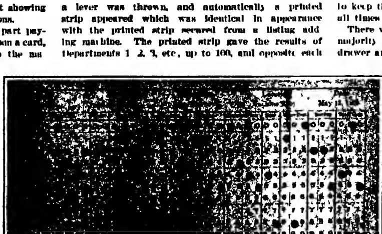
Now an inventor is working upon a principle where phonetic *sounds* can be recorded upon *strips of paper*. A man, for example, will call in his stenotypist, who will have this small device instead of the old fashioned note book and pencil. The little device will be a phonetic writer which will punch little holes in a strip of paper. These strips of paper will be fed into an automatic typewriter which will typewrite the words as the punchings in the strip will bring into play certain cards which will allow the machine to write the proper combinations.

Thirty years ago business houses had copyists who laboriously wrote pen-written letters, but to-day the stenographer fills the place. Twenty years from now bookkeepers, as they are known to-day, will be as great a curiosity as copyists are. In their place will be entry clerks of known ability and accountants who will take the machine-produced figures, and through the medium of graphic charts will present to the heads of departments a record of the previous day's business with comparative records by weeks, months and previous years. By ten o'clock each morning the record sheets dealing with vital totals will be placed upon the desks of the officials, who will then be in a position to keep their fingers upon the pulse of the business at all times.

There was a time only fifty years ago, when a large majority of small businesses were run on the cash drawer and hip-pocket principle. Conditions improved; the business men wanted a balance struck off at the end of the year. It was followed by the semi-annual inventory, after which the more progressive wanted a balance sheet every month.

Finally came the weekly report, while in some offices the daily report has arrived. But with increased competition, improved machinery and a reduction in overhead expense, and through the introduction of efficiency, the average business man, instead of delving into ancient history, a month old, will be able, after reading the latest quotations in the morning paper, to pick up his own balance sheet and know the latest quotation that his business has placed upon his ability.

With mechanical ledgers somewhat resembling telephone switchboards, bank clerks will punch cards as deposits are received or withdrawn.



The punched card principle applied to the keeping of a mechanic's account. This card has only to be run through a machine in order to obtain a printed statement of the man's output, time, and wage.

Tests of German Aeronautic Motors

OF the forty-five representative German aeronautical motors which were entered in the competition for the 50,000 mark prize offered by the Kaiser for the motor which should make the best showing in a series of tests conducted by the German government, which competition was held on the Kaiser's birthday, January 27th, 1913, but nineteen lasted through the series of tests. Of the nineteen the best showing was made by the Benz motor, a four-cylinder creation rated at 100 horse-power, designed by Chief Engineer Berger, and it emerged from the contest with a tally of [illegible] points against 170 which were chalked up for the performance against the nearest competitor. The other four prizes offered, [illegible] marks by the chancellor, [illegible] marks by the minister of war and 10,000 marks each by the secretary of the navy and the secretary of the interior were awarded to the makers of the 90 horse-power Daimler, 95 horse-power N. A. G., 72 horse-power Daimler and 70 horse-power Argus respectively. The scores of these four contestants were 170, 102, 400 and 150 points respectively.

The conditions imposed and the tests to which the motors were subjected were calculated to compare the motors with regard to their all-around efficiency for the service at hand, and to this end one of the conditions was that the entire motor must be assembled on the spot within a time limit of three days, one of the tests necessitated that the motor be sufficiently light to permit the plane in which it was mounted to coast or glide with the motor at a standstill for 15 minutes after the plane had been elevated for an equal interval, the elevating plane being fifteen per cent. In full the tests were: After erection within the three-day time limit the motors were subjected to a half-hour preliminary test running under full load on the block.

Mounted in an aeroplane the motor was run under full load for fifteen minutes and the plane guided so that it mounted a fifteen per cent grade; the motor then was stopped and the plane guided to earth, it being necessary for it to glide for fifteen minutes.

The motor was then run for seven hours without stopping.

The plane was then driven in horizontal flight for three hours, and after a stop of not half an hour another two and one half hour flight was indulged in.

The final test consisted in running the motor at top speed for half an hour.

The prize winning motor was possessed of four individually cast cylinders with overhead valves; bore and stroke were 130 and 180 millimeters, respectively, and the power developed was, as before stated, 100 horse-power at 1,250 revolutions a minute. When speeded up so that the crankshaft speed was 1,380 revolutions a minute the power was correspondingly greater. In the design of the motor no efforts have been spared to obtain reliability, as is evidenced by the duplication not only of the ignition system (two separate and distinct magnetos operating on separate plugs positioned on opposite sides of the cylinders were employed) but of the water circulating pump and the oil circulating pump as well.

By way of reducing the weight to the very last degree the cylinders are formed of a special iron alloy more easily worked than steel and at the same time more durable under the conditions. The cylinder jackets are of pressed steel and are sweated into place.

During the tests the gasoline consumption was but 210 grammes per horse-power hour, considerably less than that required for the operation of the average automobile motor. This showing is due in part to the arrangement of the intake manifold which is triple branched and innocent of sharp bends calculated to occasion banking of the mixture, and in part to the peculiar construction and location of the carbureter. The latter, or at least the larger portion of the latter, is cast integral with the crankcase so that it is in reality a part of the motor and not an appendage. The location has much in its favor since it not only economizes room and permits of a very compact construction but also eliminates projecting parts to a greater or lesser degree and provides a support for what would otherwise be a free end of the manifold, tending to eliminate vibration and strain on the manifold bolts. Moreover, as the air inlet leads from the inside of the crankcase the air supplied is heated so that a more homogeneous mixture is obtained. Air is admitted to the crank chamber through a valve provided with a protective screen.

Circulation of the cooling water is induced by a generously proportioned centrifugal pump driven from the cam shaft. A second pump of similar construction is provided for emergency use, and is driven by means of bevel gears from the magneto drive shaft. Careful balancing of all of the component parts, both statically and dynamically, has resulted in the production of a motor which is singularly free from vibration at all speeds. The weight of the motor including all piping and fittings is but 153 kilogrammes.

Wind-rolled Snowballs

"ONE of the strangest pranks of wind and snow was witnessed by residents of Davenport, Washington the afternoon of January 17th, when a strong gust of wind from the southeast blowing for a period of a minute and a half rolled thousands of snowballs from a particle of snow to big ones large as ordinary barrels and resembling in every respect huge rolls of cotton batting. A peculiarity of the unheard of prank of nature was the fact that nearly all the rolling was up hill, every south slope for miles being covered with the balls. An inch of snow of the right consistency

A group of snowballs rolled by the wind.

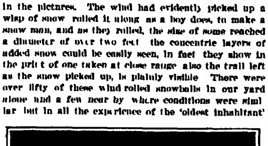
had fallen on a hard crust of snow and made possible this peculiar phenomenon. The photographs and this brief description were supplied by Edward H. Page of Davenport, Washington.

By an odd coincidence a similar freak has just been reported to the Editor by T. J. Moon of Middletown, N. Y. He writes:

"At the town of Potsdam, N. Y., on the 29th of last December occurred a light but very sticky fall of snow accompanied by a light wind which blew at right angles to the crest of a slight hill on the lee side of which were found the snowballs which are seen

View showing the concave ends of the balls.

in the pictures. The wind had evidently picked up a wisp of snow, rolled it along as a boy does, to make a snow man, and as they rolled, the size of some reached a diameter of over two feet; the concentric layers of added snow could be easily seen, in fact they show in the print of one taken at close range; also the trail left as the snow picked up, is plainly visible. There were over fifty of these wind-rolled snowballs in our yard alone and a few near by where conditions were similar, but in all the experience of the 'oldest inhabitant'



A nearer view of one of the balls.

no such peculiar occurrence had transpired before, and I have never heard of the like, so thought it might be of interest. A peculiar fact was that the rolls of snow were concave at the ends, like the vertebra of a fish, showing the size of the small bit of snow first picked up at the crest of the hill, and indicating that the increase had been in length as well as diameter."

A New Way of Studying Soils

"NO industry is so vital to the well-being of a nation as agriculture, and nothing is so vital to agriculture as the soil. From its treasury it has been estimated that we drew during the year 1909 more than $8,296,000,000, and its possibilities are as yet only partially realized. There are still in this country millions of acres which have never felt the plow, while those which are now under cultivation can, by the application of scientific principles, be made to produce many times the present value of their products. How to use and not abuse this great resource is the most important problem which faces the farmer of to-day—one worthy of the best efforts of our most profound and learned scientists, for upon its solution depends the future prosperity of the nation."

This statement from Bulletin 85 of the Bureau of Soils relating to the soils of the country. While a comparatively small percentage of the soils of the United States have been surveyed and analysed by the department, more than 800 types of soils have been discovered during the progress of the soil survey. The existence of such a large variety of soil types, each possessed of definite and peculiar characteristics, calls attention to the importance of a careful study of the soils and their relation to agriculture. The Bulletin says:

"The old idea of soil investigation was to collect samples, examine them in the laboratory, and see what differences could there be determined, the newer idea is to study the characteristics and properties of soils in the field, classify them according to obvious differences, and, with this information in hand, use the laboratory as a means of ascertaining the cause of such variations as cannot be determined in the field. This method of attacking soil problems is the reverse of the usual practice, but because of the great difficulty in duplicating field conditions, it is believed that a field examination should precede laboratory studies. The field observations can thus be used as a check upon laboratory investigation, and as an aid in their interpretation. Field studies furnish a safe and necessary anchor with which to keep the laboratory experimenter from being dashed against the rock of pure speculation. The classifying and mapping of the various soil types, together with the study of the conditions and processes under which they have been formed will furnish essential and invaluable data for the conduct of laboratory investigations. Nature's great laboratory is in the field, and a study of her methods cannot fail to offer many valuable suggestions, and, in some cases, is the only means of solving her problems. It is through a combination of field and laboratory investigations that an understanding of this extremely complex body—the soil—can be reached."

The Bulletin treats exhaustively of the soils, their origin, formation and best treatment for agricultural purposes, the great difference between the many types, and adds:

"Since the soil varies so much as regards both its inorganic and organic constituents, marked differences in character must necessarily result from the almost indefinite number of combinations which may be found. All these differences, however, may be traced to two sets of factors. First, the character of the rock or material from which the soil has been derived, and second, the processes or agencies by means of which this material has been changed from mere rock or rock debris into a medium suitable for the growth of plants. The former has to do with soil forming material, the latter with soil forming agencies. To these two groups of factors are to be attributed the numerous variations in soil conditions found over various parts of the earth.

"The importance of distinguishing between these two groups of factors cannot be too strongly emphasized. The tendency in the past has been to stress the former to the neglect of the latter and this has resulted in classifying together soils of very dissimilar character, simply because they were derived from the same rocks or from rocks which have been formed in the same manner."

The Current Supplement

IN this week's issue of the SCIENTIFIC AMERICAN SUPPLEMENT Prof. W. E. Plummer speaks in the highest terms of the valuable contributions to knowledge which have been made by amateur astronomers.—Prof. Joly in a most interesting article, tells us how nuclei of radio-active material have in the course of long geological ages produced halos in the rock containing them, by the emission of disintegration products. These halos are of perfectly definite dimensions, and display many remarkable features. They have, moreover, a definite bearing on the moot question of the age of the earth.—James Pattison, in an illustrated article, tells us of the life buoys and light ships of New York harbor.—Dr. Ferranti, in delivering his James Watt lecture on the subject of Prime Movers, made some remarkable comments on the scope and limitations of the Diesel engine. This lecture is reproduced in the current issue.—Within easy access from New York city some remarkable features of the new water supply system are being worked out at the Kensico reservoir. These are described in an illustrated article.—E. N. da Andrade reports on the latest vacuum pumps, which far exceed earlier forms in the low pressures attainable.—Dr. H. E. Hollingworth writes on Experimental Psychology in its relation to medicine.

Prize for a Gasoline Substitute

To the Editor of the SCIENTIFIC AMERICAN

Permit me to direct attention to an error in proofreading which has crept into my story appearing in the current issue of SCIENTIFIC AMERICAN and entitled "A $100,000 Prize for a Gasoline Substitute" Please note that the British Society of Motor Manufacturers and Traders has offered a prize of $10,000 and not $100,000 for a gasoline substitute As stated in the fifth paragraph of the article, it is the International Association of Recognized Automobile Clubs that has offered the $100,000 prize, the grand total therefore being $110,000.

STANLEY PETMAN, M.E

Brooklyn, N Y

Patent Office Fees

To the Editor of the SCIENTIFIC AMERICAN

As a constant reader of your paper and one who is much interested in inventors and the welfare of the patent system, I beg this space to briefly express my views on the question of increasing the fees for patent applications with especial reference to the article in your paper of February 8th, 1913 In this article you refer to the tremendous sum which has been earned by the Patent Office out of fees and turned into the Treasury This is interesting, but so far as its effect on Congress is concerned in seeking additional appropriations, it is "a last year's bird nest" as Congress is looking to results at the present time Now, as a matter of fact, I agree with the proposition that the Patent Office should not be judged by the profit it makes and am convinced that the benefits of the patents to the country at large are so great that inventors should be encouraged to the extent of large contributions from the Federal Government. But can we get the legislators to this view? I fear not. We must not only point to past profits, but we must definitely estimate future ones Now as to your suggestion that the fees should be reduced, you doubtless are aware that the Economy Commission recommended an increase to $50 while the bill introduced by Mr Bulkley and now on the calendar of the House of Representatives provides for an increase of the filing fee to $20, making a total of Government fees of $40 Suppose, however, the Government filing fee of $15 should be reduced even $1, what would the result be based on the report of the Commissioner of Patents for the year ended June 30th, 1912 The net surplus for that year is given as $68,147 20 The number of applications for patents filed that year was 79,747, so that if the filing fee had been $1 less, there would have been a net loss of nearly $12,000 instead of a surplus. Let our hopes be for better and prompter service by the Patent Office instead of for lower fees

CONSTANT READER.

A Correction

To the Editor of the SCIENTIFIC AMERICAN

In the composite price list of American cars, published in the January 11th issue of SCIENTIFIC AMERICAN, you published some erroneous figures with reference to the prices on Packard cars

Your Packard figures include a "25" roadster at $950, an "18" touring car at $2,800, and a "30" touring car at $3,700 We manufacture only maximum service cars, and you are doubtless aware that it would be impossible for anyone to market such vehicles at the prices named and remain long in business. Our line of motor carriages consists of a "38" at prices ranging from $4,150 to $5,400 and a "48" at prices from $4,650 to $6,100

The inquiries which we have received since the appearance of your price list speak well for your circulation but are causing us serious embarrassment. We feel confident that your own sense of fairness will induce you to correct the erroneous impression which has been created among your readers

Aeroplane Design

To the Editor of the SCIENTIFIC AMERICAN:

One of the most important and at the same time one of the most intricate problems of the aeroplane is the proper shape for the supporting surfaces The cut-and-try method of testing in vogue at the present time has been the means of supplying a deal of valuable data, but, as will be readily understood, with the most delicate instruments for measuring the air pressure, and with the utmost care in the reading of these, the method can give only approximate results, and is therefore inadequate to the present need of a designer.

In place of this arbitrary and wholly artificial means of testing, the writer would direct the consideration of those interested in the practical development of the aeroplane to another, which in addition to the advantage of giving exact results, is simple and direct.

If a rectangular piece of silk be suspended in a gentle current of air, it takes a curved form as the result of the two forces which act upon it These forces are (1) its weight acting vertically downward with a pressure equal in intensity at all points on the surface, (2) the pressure of the air This latter force is horizontal in direction at the extreme front edge of the silk, but, just as the air flows beneath the fabric it is deflected slightly downward as a result of its reaction with the surface This downward movement of the air particles is communicated to the air below not immediately adjacent to the silk The upward component of the pressure of the air consequently diminishes, with the result that more and more surface is exposed to maintain the equilibrium

In the above experiment, for the sake of clearness, we have dealt only with the air below the silk The same method of reasoning is equally applicable to the upper side. The air streams are flowing horizontally at the front edge, immediately behind it they are pulled downward by the displacement caused by the cross section of the arc This pull downward is a pull upward for the plane The air would now flow parallel with the surface, and would exert no further lift whatever were there no further curve in the surface, but the flexible silk automatically adjusts itself by means of its weight, falling and increasing the cross section until the balance is restored

We would emphasize then the fact that the curve taken by a flexible surface of uniform weight suspended freely by one edge in a current of air is a graphical representation of the two forces which act upon it, and that at all points on the surface the two forces are in equilibrium Also, that for the particular conditions under which the experiment is conducted, the balance is maintained with a minimum of drift, for there is of course a decrease in the absolute drift component of the air pressure, *proportional to the decrease in the absolute lift.*

The application then of the method of the experiment, as a system of aeroplane supporting-surface graphing, is obvious, for weight balanced by air pressure is a condition identical with the principle underlying the operation of the aeroplane.

A rectangular piece of stout fabric of the actual width to be employed in the construction of the machine itself could be suspended by one edge in a wind tunnel, and the load, that *is weight per square foot of supporting surface*, distributed uniformly over the whole area by passing flat metal bars through loops in the upper side of the fabric By placing these parallel with the front edge, and by spacing them short distances apart, the surface would be entirely flexible, free to take up the position in which its own weight would balance the reaction of the air upon its surfaces. This position could be fixed photographically and the pattern thus obtained used for the construction of a rigid plane

Such a method undoubtedly would be of incalculable use to a constructor, for not less important than the facility of the system is the interchangeability of the elements involved. As to the question of the angle of incidence, it will be readily seen that this could be adjusted as desired in either or both of two ways by altering the load or by changing the relative speed of the air Thus, a designer would be enabled to produce the most efficient wing form for any possible combination of flight conditions.

It is interesting in this connection to notice the high degree to which the above principle has been carried in the structure of that bird of the water, the sailing vessel, whose wing, automatically varying to the most favorable form under any conditions of wind pressure, and direction of wind pressure, can propel the craft almost into the teeth of a wind In fact, no better proof of the practical worth of the idea suggested could be wished for than this, that no rigid surface, plane or curved has been found to give the all-round efficiency of the flexible sail

It seems probable even that with proper observance of the perfection of detail required in the design of aerial vehicles, substantially the same method of leaving the fabric flexible might be applied with interesting results to the construction of an aeroplane's wings However, it seems probable that, as in both classes of vehicles the best efficiency could only be obtained by altering the length of the chord, the best way would be, as is the present practice, to construct the machine rigid and designed for the highest speed the craft is meant to attain, since it is of course at the maximum speed that exquisiteness of design is most required Moreover the rigid structure would seem to be particularly adapted to the aeroplane, since full speed when once attained is as regular as that of the highest types of automatic machinery

For the verification of the conclusions reached in the preceding, the writer would point out that the curvature taken by the surface in the experiment is a modification of one of the conic sections known as the semi-parabola, and would refer to the fact that this curve is universally acknowledged by mathematicians and has been experimentally proved to be the basic curve for wing sections. Indeed, it would be a comparatively simple matter to plot the curve for any combination of weight and horizontal pressure, were it not for the fact that the action and reaction of the particles in a fluid are exceedingly complex and consequently considerably modify the result. It is in overcoming this difficulty that the method outlined above should prove so effective

Are Levees a Failure?

To the Editor of the SCIENTIFIC AMERICAN

All rivers subject to floods if they flow through flat lands, form a sort of natural levee This process is going on at my office door on the east bank of the Greenbrier River, on a small scale When the river is in flood the plain on this side is covered with water Where the rapid current of the river comes in contact with the more quiet water on the plain or bottom land and is checked by it, a line of sediment is deposited thus forming a natural levee Left to nature, the river bed the bottom land, and the natural levee rise together keeping a sort of relation to one another If you build an artificial levee you interfere with this relation, and as the bed of the river rises by sediment, you must keep on adding to the height of the levee until in time the bed of the river will be above the country around, because the flat country not getting its proportion of deposit does not rise as it did before the levees were constructed by man Now to some extent the artificial levees make more current and keep the deposit from forming so rapidly in places but it makes the condition worse in others, when current is sluggish From this theory the remedy would be to control the flood waters about the heads of the streams by dams No large river has ever been successfully leveed, nor ever will be, for the reason given The attention of people living along rivers subject to devastating floods should be called to this scientific fact

The Spring Wheel

To the Editor of the SCIENTIFIC AMERICAN

Referring to letter from Mr O F Fischer in your issue of February 1st under the title of The Fallacy of the Spring Wheel It would hardly be fair to the automobile world to allow a conclusion so erroneous to go unanswered

The basis from which your correspondent reasons implies that there is but one kind of spring wheel and that that kind is of the crudest and most imperfect form of wheel The only arrangement that he indicates is one in which the springs at the top of the wheel and those at the bottom of the wheel carry the load and he practically assumes that there is no other method of creating a spring wheel Having started out from an erroneous basis he must necessarily reach an erroneous conclusion

Everyone in the least degree familiar with the spring wheel art knows that any radial arrangement of springs by which the springs at the top and bottom of the wheel carry the load chiefly, or any arrangement in which the load is passed from one spring to another or from one series of springs to another is a long ways behind the present condition of the art

Further, anyone who has studied the question and kept *au courant* with the art is familiar with the fact that the highest type of spring wheel requires all of the springs to assist equally at all times in carrying the load and in meeting the shocks and further that in the highest type of spring wheel when the wheel is operated over a perfectly level road the springs are not flexed in the least degree, but remain stationary just the same as the eliptical spring

Your correspondent falls into another very great error in assuming that a spring wheel is required to effect the same amount of resilience as the elliptical springs of the car It is a well-known fact that the resilience offered by a pneumatic tire is but a small percentage of that of the ellipitical springs and thus if the spring wheel reproduces the same shock-absorbing qualities as the pneumatic tires it answers the purpose perfectly though it affords but a small percentage of the resilience that the elliptical spring affords

The writer is thoroughly familiar with the spring-wheel art and he is fully aware that there is no subject in which the automobile trade generally is so misinformed and so needlessly skeptical as to the spring-wheel art, and he therefore wishes to state that every owner of an automobile and everyone interested may take heart, notwithstanding the oft-expressed impossibility of a spring wheel as the spring wheel will supplant the solid wheel with the solid tire and solid wheel with the pneumatic tire beyond the least shadow of a doubt and no one can know the facts of which the writer is possessed without realizing the correctness of this statement

For the information of those who are in doubt the writer will further state that there is already on the market in a small way a spring wheel which meets the requirements above outlined and which is rapidly gaining headway, and it is only necessary for anyone interested to keep his eyes open as they will be seen in large quantities right in New York city within a very short time

How Catskill Water is Being Brought to New York

Phenomenal Growth of New York.

GREATER NEW YORK is adding to its population at the rate of 140,000 people per year—an increase which is absolutely without precedent or parallel in the growth of the world's great cities. Such an increase as this renders enormously difficult the problems of housing, food supply, transportation and proper hygiene. For many years past and long before the rate of increase had reached its present proportions, the city authorities have been at their wits' end in endeavoring to enlarge the various facilities of the city so as to keep pace with the demands of its ever-growing population.

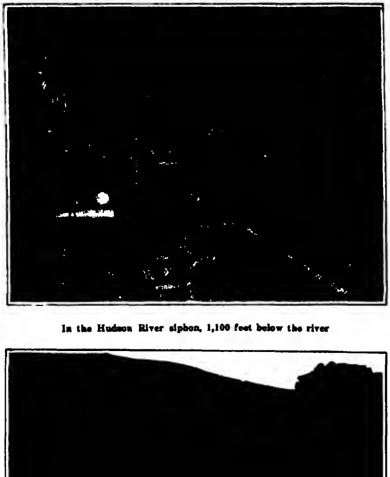
The Peril of Water Famine.

With the exception of rapid transit there is no problem of the city's need which has proved more serious, more pressing or more difficult, at least in recent years, than that of providing an adequate supply of pure drinking water. At frequent intervals the city has been threatened by that justly dreaded terror, a water famine—justly dreaded because a shortage, to say nothing of a total failure of water, might mean an outbreak of pestilence, to say nothing of the loss and inconvenience occasioned by the shutting down of the various factories and smaller industries which a shortage of the water supply would necessitate.

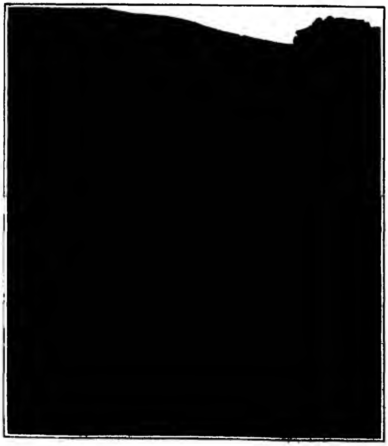
It is not so very many months since the whole city was watching with a very anxious eye, the steady fall of the water levels in the various reservoirs of the Croton watersheds, for a season of drought extending far into the winter had served to bring the hitherto remote peril close to its very doors.

In view of the rapid growth of the city it was evident at the outset that any adequate scheme for increasing the water supply must be made upon the broadest possible scale, and that it should make provision not only for the immediate needs of the city, but for those of many a decade to come. This has been done by the Board of Water Supply, and it is the purpose of this and the following article to show that the project of bringing the Catskill Mountain water to New York has been considered on such adequately comprehensive lines that the possibility of any shortage of water in this great city has been removed into the very far future.

On May 14th, 1905, the State Water Supply Commission approved of the application of the Board of Water Supply of this city for obtaining a daily supply of 500,000,000 gallons of water from the Esopus, Rondout, Schoharie and Catskill creeks in the Catskill Mountains, at an estimated cost of $161,857,000. In 1910 a plan for the distribution of the water throughout Manhattan, Queens and the Bronx by a deep pressure tunnel was approved by the Board of Estimate and Apportionment. The additional cost of this scheme is $15,000,000.



In the Hudson River siphon, 1,100 feet below the river



Placing the nine and one half foot steel pipe—Foundry Brook siphon.

The New Scheme of Water Supply

The new supply of water, of the finest mountain quality, is to be taken from four watersheds, having a total area of nearly nine hundred square miles. The total estimated capacity of these four gathering grounds is, even in a series of unusually dry years, equal to supplying 770,000,000 gallons daily. Reservoirs will be built as they are required, in each of these basins, and they will be connected by aqueducts. For the present, the Esopus watershed only is being developed. In a series of dry years this watershed can furnish a daily supply of only 250,000,000 gallons, but the aqueduct leading to the city is being built of double that capacity, or 500,000,000 gallons daily. The first contract for construction was let at the close of 1906. In 1907 to 1908 about five per cent of the work was completed from Ashokan reservoir in the Esopus watershed to Croton Lake. By the end of 1909 22 per cent was done, 60 per cent at the close of 1910, 78 per cent by 1911, and at the present time about 95 per cent of the work is done. The delivery of water into the Croton reservoir, which will be possible this year, will prevent any possibility of water famine during the completion of the new aqueduct to New York.

The system under construction and now nearing completion consists of a large reservoir in the Esopus basin, an underground aqueduct seventeen feet in diameter by which the water is led for sixty-four miles to another large basin, the Kensico reservoir, which will serve for emergency storage, a third reservoir situated about fifteen miles south of Kensico and just over the New York city line, known as the Hill View reservoir, which will equalize the difference between the use of water in the city, which, of course, varies from hour to hour and from day to day, and the steady flow coming in from the aqueduct. Between Hill View and the city the system consists of a deep circular, high-pressure tunnel, through which the water will be led beneath Manhattan, to be distributed by surface mains throughout that city, and also throughout the other districts of Greater New York.

The Ashokan Reservoir.

The great Ashokan reservoir is situated about fourteen miles west of Kingston on the Hudson River. Its cost is $18,000,000, and it will hold sufficient water to cover the whole of Manhattan Island to a depth of twenty-eight feet. The water is impounded by the Olive Bridge dam, which is built across Esopus Creek, and also by the Beaver Kill and the Hurley dikes, which have been built across streams and gaps lying between the hills which surround the reser-

The Olive Bridge dam, 4,650 feet long, 220 feet high.

Diamond drill boring horizontal hole 1,100 feet below Hudson River

voir. By the first of January, this year 73 per cent of this work was done. The dam is a masonry structure 190 feet in thickness at the base and 23 feet thick at the top. The surface of the water when the reservoir is full is 590 feet above tide level. The total length of the main dam is 4,650 feet, and the maximum depth of the water is 190 feet. The area of the water surface is 12.8 square miles, and in preparing the bottom it was necessary to remove seven villages, with a total population of 2,000. Forty miles of highway and ten bridges had to be built. In the construction of the dam and dikes it was necessary to excavate nearly 3,000,000 cubic yards of material and 8,000,000 cubic yards of embankment and nearly 1,000,000 cubic yards of masonry had to be put in place. The maximum number of men employed on the job was 3,000.

The Ninety-two Mile Aqueduct

The water is conducted from Ashokan reservoir as a huge, underground, artificial river. The aqueduct is ninety-two miles in length from Ashokan to the northern city line, and it should be explained that it is built on a gentle grade, and that the water flows through this at a slow and fairly constant speed. The aqueduct contains four distinct types: the cut-and-cover, the grade tunnel, the pressure tunnel, and the steel pipe siphon. The cut and cover type, which is used on fifty five miles of the aqueduct, is of a horseshoe shape and measures seventeen feet high by seventeen feet six inches wide, inside measurements. It is built of concrete and on completion it is covered in with an earth embankment. This type is used wherever the nature of the ground and the elevation allow. Where the aqueduct intersects hills or mountains, it is driven through them in tunnel at the standard grade. There are twenty four of these tunnels, aggregating fourteen miles in length. They are horseshoe in shape, seventeen feet high by thirteen feet four inches wide and they are lined with concrete. When the line of the acqueduct encountered deep and broad valleys, they were crossed by two methods. If suitable rock were present, circular tunnels were driven deep within this rock and lined with concrete. There are seven of these pressure tunnels of a total length of seventeen miles. Their internal diameter is fourteen feet, and at each end of each tunnel a vertical shaft connects the tunnel with the grade tunnel above. If the bottom of the valley did not offer suitable rock for a rock tunnel, or if there were other prohibitive reasons, steel siphons were used. These are nine feet and eleven feet in diameter. They are lined with two inches of cement mortar and are imbedded in concrete and covered with an earth embankment. There are fourteen of these pipe siphons in a total length of six miles. At present one pipe suffices to carry the water. Ultimately three will be required for each siphon.

Of the many siphons constructed, by far the most interesting and difficult is that which has been completed beneath the Hudson River. The preliminary borings made from scows in the river showed that great depths would have to be reached before rock sufficiently solid and free from seams was encountered to withstand the enormous hydraulic pressure of the water in the tunnel. After failing to reach rock by the scow drills two series of inclined borings were made from each shore, one pair intercepting at about nine hundred feet depth and the other at about fifteen hundred feet. Both showed satisfactory rock, and accordingly a shaft was sunk on each shore to a depth of approximately eleven hundred feet, and then a horizontal tunnel was driven connecting the two. It is of interest to note that because of the enormous head, which must be measured from the flow line far above the river surface, the pressure in the horizontal tunnel reaches over forty tons per square foot.

This will form part of a system of new highways

Driveway along crest of Olive Bridge dam

Ashokan reservoir—Upper gate chamber

Constructing a steel and concrete section of aqueduct

This section consists of a steel pipe, lined internally with two inches of cement mortar, and embedded in reinforced concrete.

Kensico Reservoir

Next to Ashokan the most important basin is the Kensico reservoir, which lies east of the Hudson and is situated thirty miles north of the City Hall. It will hold sufficient of the Catskill water to supply the city for several months. Its purpose is to act as an emergency storage reservoir, so that if it is necessary on account of accident to interrupt the flow in the seventy seven miles of aqueduct between Kensico and Ashokan, this can be done without interrupting the city supply. The cost of this work is $8,500,000.

The reservoir will be formed by a huge masonry dam across the valley of the Bronx River. The surface of the water will be at an elevation of three hundred and fifty five feet above mean sea level and will cover 2,218 acres. It will contain when full about 40,000,000,000 gallons, of which 30,000,000,000 gallons, or sixty days continuous supply at 500,000,000 gallons daily, will be available. The main dam will be eighteen hundred and forty three feet long. The total height will be three hundred feet. It will be two hundred and thirty feet thick at the base and twenty eight feet thick at the top. The average depth of the reservoir will be one hundred feet, and its maximum depth at the wall of the dam will be one hundred and fifty five feet. An interesting feature of the construction is that the entire dam will be divided into sections by transverse expansion joints, which will be placed about eighty feet apart longitudinally. On one side they will be faced with concrete blocks forming a series of vertical tongues and grooves against which the masonry of the other side will be built. Near the up-stream face will be a copper strip which will cover the expansion joints and act as a water stop, the strips continuing from the bottom to the top of the dam. In order to catch any water that may seep through from the up-stream side, diagonal wells will be built fifteen feet apart, measured longitudinally. They will be formed of porous concrete blocks. They will reach from the top of the dam to a longitudinal inspection gallery at about the level of the reservoir bottom, which will in its turn be connected with a transverse drainage gallery,

which will lead to the downstream base of the dam. This will prevent any seepage entirely through the wall and will avoid that discoloration which is liable to mar the architectural beauty of structures of this kind.

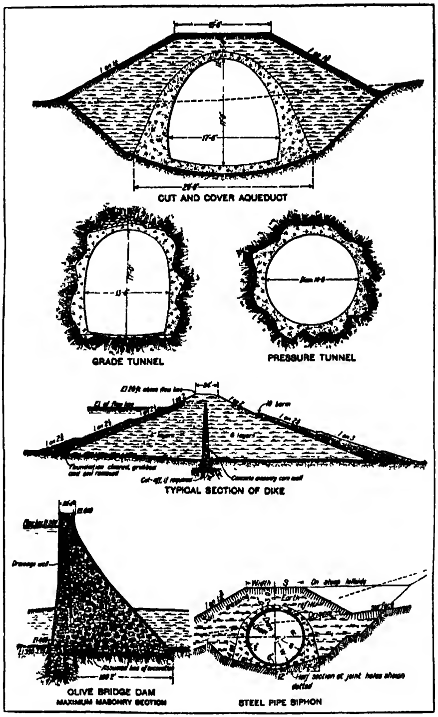
Aeration and Filtration.

Both at the Ashokan and Kensico reservoirs aerators will be built, each of which will be capable of passing and treating all the water which will flow in the aqueduct. The aerator is a large rectangular basin five hundred feet by two hundred and fifty feet, containing about eighteen hundred nozzles, through which jets of water will be thrown into the air. The nozzles will be of such form that the water will be divided into a fine spray and this will permit of a thorough admixture of the oxygen of the air and the removal of gases and matters which would cause taste and odors. For the present no provision will be made for filtrating the Catskill water but provision has been made for a filtration plant by the purchase of three hundred and fifteen acres of land near Tarrytown, adjacent to the aqueduct.

Hill View Reservoir

From Kensico the water will flow to the Hill View reservoir which will serve to equalize the difference between the amount of water used in the city and the amount of water flowing in the aqueduct. Also it will furnish a great quantity of water should there be an immediate demand such as occurs during a great conflagration. Its capacity will be 900,000,000 gallons. The reservoir is divided into two basins so that one may be used while the other is being inspected for repairs. The aqueduct is carried within the wall which divides the two basins, and the aqueduct water can be passed through the reservoir and delivered directly into the city tunnel.

Our thanks are due to Mr. Alfred D. Flinn, Department Engineer of the Board of Water Supply, for courtesies extended during the preparation of this article.



Sections of the aqueduct and dams—Catskill water supply

The International Building Exposition in Leipzig

An International Building Exposition will be held in Leipzig this year. The time during which applications for space may be submitted has recently been extended until the end of February in order to permit firms which have not yet submitted applications to make good this omission. Space to the value of more than a quarter of a million dollars has already been allotted and the demand is still brisk.

Dr. Probst of Berlin, whom the directors sent to this country to arouse American interest in the exposition and to secure adequate participation therein by the United States Government, cities, associations, industrial firms, etc., has described his travels in a lecture, delivered in Leipzig, of which the following is an abstract.

The United States Government shows much interest in the exposition. The cities of New York, Chicago, Philadelphia, and San Francisco, the American Bridge Company (the oldest and greatest of American bridge-building firms), and the Canadian Railway Company will exhibit typical models and photographs of "skyscrapers," bridges, city views, schools, waterworks, etc. Very complex problems are presented to American engineers by peculiar geological, climatic and traffic conditions. The exhibition will show how these problems are solved in the eastern, central, and western States.

Both the rapidity and the methods and materials of American building are greatly influenced by the exceedingly high rate of wages ($5 or $6 per day) and by the almost total absence of legal building restrictions. The high cost of labor has led to the substitution of machine work for hand work as far as possible. The lack or deficiency of building laws in many places has permitted speculative builders to erect unsafe structures. A striking instance of this was revealed after the earthquake in San Francisco, where foundations of many of the fallen buildings were found to have been constructed in the most reckless manner. Praiseworthy energy was then displayed in the erection of a new city which may be regarded as structurally unexceptionable. Examples of the new buildings of this beautiful city will be represented at the Leipzig exposition.

Almost everywhere in America Dr. Probst noted with approval a sharp demarcation between business sections and residence sections, which does not exist in Europe outside of England, but he was unfavorably impressed by the lawless co-mingling of ordinary four-story and five-story buildings with towering structures of thirty or more stories. American engineering societies, however, are beginning to give attention to aesthetic and hygienic considerations which have hitherto been ignored, and many of their members will visit the Leipzig exposition where these matters will be fully illustrated.

Dr. Probst finds ferro-concrete the building material most extensively used in America, and mentions an ingenious device employed in the construction of most large buildings and consisting of a central tower from which the concrete flows through a movable spout to any spot where it is wanted.

The projected Chicago ship canal will be well represented at Leipzig. Dr. Probst regards Canada with its great fertility and scenic beauty as the land of the future and the most promising field of activity for the building engineer. In conclusion, Dr. Probst named, as the two most eminent American building engineers, Lindenthal and Hornbostel, both of whom will exhibit models of their works at the coming Leipzig Building Exposition.

Supplying a Metropolis With Mountain Water

How Mining Operations Are Being Carried on Through the Heart of New York

THE preceding pages tell how the new aqueduct is being constructed from the Catskill Mountains down to the New York city line, where, at the Hill View reservoir the waters will pause before taking their plunge into the heart of the city

The problem of admitting so large a flood into the metropolis is no small one, particularly when the chief demand for the water will come from those sections of Greater New York which lie many miles away For the present at least little if any of the Catskill water will be used in Manhattan and the Bronx but most of it will be consumed by the boroughs of Brooklyn, Queens, and Richmond The Water Waste Campaign which has been carried on for the past few years has so far reduced the consumption of water that the Croton system, which can furnish steadily 350,000,000 gallons of water per day, can easily take care of the immediate wants of Manhattan and the Bronx as well as the demand from these two boroughs for many years to come It is not likely that the population in Manhattan will increase much unless it undergoes a marked vertical growth for now there are practically no more vacant lots to be built upon So that in estimating the future demands upon the Croton system we must consider chiefly the growth of population in the Bronx In the other three boroughs of the city however there is a present demand for water and the probability of large increases in population in coming years.

To conduct the Catskill water into Brooklyn and Queens, it was decided to build a trunk line, so far beneath the surface that there would always be 150 feet of good solid rock for the roof of the tunnel, and provide a course for a subterranean river which could be tapped as needed for the city's supply, and which, at the same time, would be so completely buried that it would never menace the safety of structures above it. When this tunnel is completed it will be one of the most durable pieces of work ever constructed by man for practically nothing but an earthquake can destroy it and even this possibility is very remote, for the rock underlying New York is of very early formation and not at all liable to seismic disturbance And so the city tunnel of the Catskill aqueduct is being bored through the rock on the average of 200 to 250 feet below the surface except in places where the nature of the rock is of such a character as to call for a much greater depth

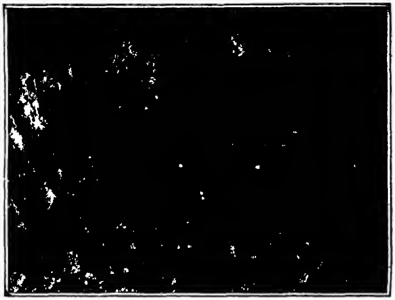
The first dip takes place just above the Harlem River, where the tunnel drops down 382 feet below the ground level. Then it runs practically horizontally until it passes the dip in the rock under 125th Street Thence it rises again and maintains a practically constant level of 200 feet under the city, until it arrives at the ancient bed of the East River A glance at the map of New York city will show that the East River makes a decided turn about the lower east side or "heel" of Manhattan. In pre-glacial times, the East River had no elbow in its course, but ran directly across the heel of Manhattan, and it wore away the rock in its bed to considerable depths. However, the large deposits of earth and rock carried by the glaciers caused the river to be pushed eastward out of its normal channel and over the solid rock beyond When

The height of the Woolworth Building equals the depth of the deepest aqueduct shaft in New York.

borings were made for the aqueduct through this section of the city it was found necessary to lay it at a depth of about 750 feet below the surface As indicated in the accompanying drawing, much of the rock through this section is decayed and unfit to form the walls of a high pressure aqueduct which is being built to last for all time The present channel of the East River on the other hand passes over solid rock and is comparatively very shallow Seven hundred and fifty feet is an enormous depth, second only to the great siphon under the Hudson River which is 1114 feet below the river surface It so happens that the deepest shaft ever sunk in New York city equals the height of the tallest building in the world To illustrate this enormous depth, our artist has taken the liberty of building the Woolworth Building topsy turvy, that is from the ground down at the Clinton Street shaft at the west bank of the East River Enormous as is the building yet it barely reaches the aqueduct at this point Evidently there will be plenty of cellar room over the tunnel and yet it is worth noting the aqueduct follows the street lines so as not to trespass on private property!

Arrived in Brooklyn the aqueduct rises again to within two or three hundred feet of the surface and is pushed as far as it is possible to carry it in solid rock and yet communicate with the surface This limit was found to be at the junction of Flatbush and Third avenues. Here it was necessary to go through 215 feet of overlying earth before coming to the rock The caisson method had to be resorted to and the caisson was sunk over 100 feet below the water line before rock was reached Considerable difficulty was here experienced in sinking the shaft to the rock because it called for the use of pneumatic pressure that taxed the endurance of the workmen to the limit From here on the water will be conducted through pipes laid in a trench of a moderate depth below the surface From the foot of Seventy-ninth Street Bay Ridge the conduit will be run across the Narrows to Staten Island through a pipe 36 inches in diameter provided with flexible joints and laid in a submarine trench The details of this section of the work have not yet been given out However tests have been made to discover at what depth the pipe line under the water must be buried It is evident that it must lie far enough below ground to prevent its being entangled with anchors from large vessels that may have to anchor in the Narrows The matter has been thoroughly investigated and practical tests have been made by dragging anchors of large size along the bottom It has been determined that if the pipe line is buried at least eight feet under the bed it will be entirely safe On the Staten Island side a 48-inch pipe will carry the water on up the hill and through a tunnel into Silver Lake reservoir 120 miles from the source in the Catskills.

The greatest interest in this city section of the aqueduct attaches naturally to that part which is being excavated through solid rock under the busy city It is a surprising fact that a work of such magnitude can



"Holed through" from shaft 16 to shaft 17. Dangerous rock overhead due to vertical seams.

Permanent channel iron support for a treacherous roof. The beams will be imbedded in the concrete lining.

be carried on directly under our feet without inconveniencing us in the least. The only surface evidence of the deep rock tunneling is to be found at the various shafts which are located in parks or public squares. The principal difficulty that presented itself at first was the question of storing explosives for a work of such great proportions. To keep the necessary explosives on the surface was to harbor constant menaces to the lives of the citizens. The matter was finally solved by placing the dynamite magazines far under the surface in the rock and setting the doors to these magazines so they will automatically close in case of an explosion and trap the hot and poisonous fumes in the rock chamber where they can do no harm to the workmen. The idea was borrowed from European practice where mining operations are conducted close to and sometimes directly under large cities. Access to the dynamite chamber is had through a zigzag drift. At each turn of the drift a pocket is excavated, and the chamber itself is made of large capacity. In this chamber the dynamite is stored under a protecting roof to keep off any fragments of rocks that might fall when jarred by the shooting in the tunnel. At the entrance of the drift a very substantial concrete bulkhead is built and in this is a low doorway. The door is of massive construction built of I-beams sixteen inches deep and spaced apart with oak beams twelve inches square. The door has beveled edges, so that it will seat itself snugly in the doorway. The door is always kept open at an angle of about 15 degrees. In the magazine a thousand pounds of dynamite may be kept at a time. Should this be exploded, the explosion wave would have to travel down the zigzag passage and would lose much of its force at each abrupt turn, finally striking the door with greatly diminished energy. The door would be slammed shut by the blast of air issuing from the drift and would then be held shut by the gases of the exploded dynamite. A magazine of this sort has been constructed near the foot of each shaft—not at the foot however, for fear that in case of a mishap it might block the escape of the men. The magazines have been tested by exploding a number of sticks of dynamite around the first bend in the drift, and in every case the door has closed just as expected.

The work through the rock is being pushed very rapidly, at some of the shafts between 800 and 1,000 pounds of dynamite have been used daily. Within the last year millions of pounds of dynamite have been exploded under the city, while most of New York was totally oblivious to the fact. Already a number of the tunnel sections have been "holed" through. To expedite the work, one contractor is using an interesting form of shoveling machine built especially for this work so that it may be taken down the comparatively narrow shaft and be assembled to work within the small diameter of eleven feet, which is the size of the tunnel at the particular point where this machine is now being used. A photograph of this machine is shown herewith, and also a drawing illustrating the mechanism. The machine is controlled by a single operator and does the work of six laborers. It is provided with a double shovel A and B. The section A digs up the rock and throws it upon the scoop B, which in turn empties its load upon a traveling chain conveyor C, the latter delivers the load into muck cars at the back of the shoveling machine. The letters B, B^1, B^2, and B^3 show the successive positions of the scoop. The forward section A is carried upon a crank shaft D, which is revolved through the arc indicated by the arrow. Another arrow line shows the course of the front edge of the section A. The forward end of the scoop B rests upon the heel of the section A, while its rear end is mounted upon a shaft E, which travels in a guideway F. The forward section A is connected to the shaft E by means of side plates, indicated by dotted lines, so that as the crank shaft D revolves, the slide shaft E is obliged to run up the ways F, as indicated by the letters E^1, E^2, and E^3. The section B is equipped with a small arm G, which carries a roller that is adapted to engage the cam groove H, causing the scoop B to turn over as indicated in the dotted view B^3 and empty its load upon the traveling conveyor. The machine is mounted on a turntable, so that it may be turned about in any direction.

Looking down the 441-foot shaft at 149th Street.

Reinforcement for the caisson at Flatbush and Third avenues.

Shoveling machine for removing the broken rock and loading it into cars.

Some of the work on the city pressure tunnel has been hurried so far that certain sections are now being lined with concrete. The forms used for this purpose are very interesting. Our front page illustration shows their construction. They cover 120 feet altogether and are arranged in two sections, sixty feet of the lower half of the tunnel being concreted in an advance of sixty feet of the upper part. The first step is to lay the "invert," that is, a narrow segment of the lining running along the bottom of the tunnel. This,

Section along the city pressure tunnel, showing how it has to dip down under the pre-glacial bed of the East River.

The Heavens in March

Eclipse of a Star by One of Jupiter's Moons

By Henry Norris Russell, Ph D

A VERY unusual piece of astronomical work, from a part of the world in which little has previously been done, deserves description this month. Though published in the German *Astronomische Nachrichten*, it originates in Chile where Dr Ristenpart a German astronomer of distinction, is in charge of the observatory at Santiago.

On the night of August 13th, 1911, the third satellite of Jupiter Ganymede, passed directly in front of a star of the seventh magnitude, in the constellation Virgo, and for observers in the southern part of the Earth, actually hid the star for more than four minutes.

The circumstances of this remarkable occultation were carefully calculated in advance by Banachiewicz, and it appeared that the best observing stations would be in South America Dr Ristenpart, with great energy, set about the organisation of observers throughout Chile, and it is undoubtedly due to his zeal and forethought that the important results which we are to describe were obtained.

Why it was important to have observations made at as many places as possible appears from the fact that since Ganymede is much smaller than the Earth, its shadow if we may so describe the region from which at any moment it conceals the star is only a little more than 4,000 miles in diameter

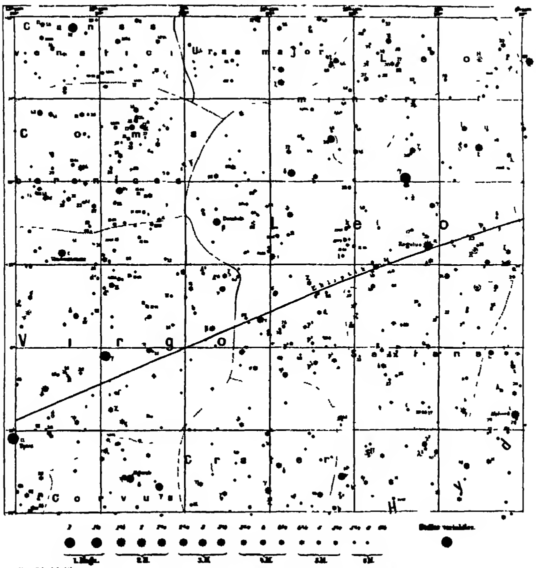
As Jupiter and its satellite moved, this 'shadow crossed the Earth its center passing over the southern extremity of South America a little north of the Straits of Magellan while its northern limit reached barely to the boundary between Chile and Peru Observers at southern stations would therefore see the satellite pass almost centrally over the star while for those in northern Chile, the latter would be concealed for a much shorter time behind the northern edge of Ganymede

By comparison of the duration of the occultation as seen from different places, it should therefore be possible to obtain very accurate information regarding the size and shape of the eclipsing body In spite of unfavorable weather and other difficulties, the various observers—mostly school teachers or amateur astronomers—were able to obtain reliable observations at five stations, extending almost along the same meridian for 1,000 miles. Except at Santiago, the observers had only small telescopes of about four inch aperture, with which the satellite could not be distinguished, as regards its appearance, from the star, except that it was a little brighter The two came closer together until they could no longer be distinguished, but formed one mass of light. Then, suddenly, the light diminished to about one half, this being, of course, the real instant when the star vanished behind the satellite. After a time the light increased again as the star came out, and then the mass of light gradually separated into two points.

In addition to these visual observations a number of photographs were obtained by Dr Zurbellen, which defined very accurately the relative positions of the star and satellite before and after their conjunction, and made it possible to calculate just how far apart they must have appeared at any time.

Working along these lines, Dr Ristenpart finds that, in order to get a satisfactory agreement between theory and observation it is necessary to assume that the satellite, like Jupiter itself, is flattened at the poles, for otherwise the calculated length of the occultation at the northernmost station, where the star appeared to pass just inside the satellite's disk would be much longer than the observed time As the rate of motion of the satellite is accurately known the maximum length of the occultation affords a very precise measure of its diameter Dr Ristenpart finally concludes that the equatorial diameter of the satellite is 4 700 miles, and the polar diameter 4,300, so that it is a little more flattened in proportion to its size than Jupiter himself. The diameter of the satellite was previously supposed, from micrometer measures, to be about 3 000 miles, and the difference between this and the new value is surprisingly large, but owing to the method of observation Dr Ristenpart's results seem to be entitled to very serious consideration The mass of this satellite is known, from its attraction on the other satellites to be about 1/12,000 that of Jupiter or a little more than 1/4 that of Mars. But, according to the results just given it is a little larger than Mars. This would make its density less than ½ that of Mars, and actually less than that of water—intermediate between the densities of Jupiter and Saturn. Even with this low density, it must be in rapid rotation with a period not more than ten or twelve hours, to account for the polar flattening.

It is perhaps most interesting of all to note that, according to the most definite of the observations, the disappearance of the star behind the satellite was almost instantaneous, the loss of light lasting only a second or so. This means that the apparent diameter of the star was not more than 1/300 that of the satellite, in other words, less than 1/500 of a second of arc This is quite what is to be expected for a star of the seventh magnitude, but it is interesting to have the extreme smallness of the apparent diameter of a star confirmed by direct observation.



From Schurig's Atlas

THE HEAVENS IN THE REGION OF LEO AND VIRGO

The Heavens.

We give again this month a detail map showing a portion of the sky which is now favorably placed for evening observation. Any one familiar with the constellations can easily pick out upon it the Sickle of Leo toward the west – that is, on the right for on maps of the sky toward which we look *upward* the position of east and west if the north is at the top is necessarily different from what they would be on maps of the Earth's surface at which we always look downward

Among objects of telescopic interest here are Gamma Leonis, in the Sickle a very well known binary pair, now separated by 15 seconds, and in very slow motion so that a complete revolution can hardly take less than 1000 years The bright star Regulus, at the end of the handle of the Sickle,' has a companion of the eighth magnitude a little less than 3 minutes away which in spite of its great distance from its primary shares the proper motion of the latter and is doubtless really as near it as it appears to be Fifty four Leonis in the northern part of the constellation, is a pretty pair with components of the fourth and sixth magnitudes 6 minutes apart

South and east in Virgo the star γ is a famous binary which has been followed for the greater part of its period of one hundred and ninety years At present the two stars are at their widest separation about 6 seconds apart and can be separated with a very small telescope as can the pairs previously mentioned In 1836, however they were less than one tenth as far apart as now and could only be divided by the most powerful instruments of that day

ξ Ursae Majoris which may be found near the northern edge of the map just north of δ Leonis, is another very fine binary pair with a period of sixty years The components are now at their greatest separation—nearly 3 seconds and can be resolved by instruments of very moderate power

The Planets.

Mercury is evening star until the 27th when he passes through inferior conjunction and becomes a morning star He may best be seen about the 10th, when he sets about 7 30 P M Though only 18 degrees from the Sun he is north of him, and very bright (excelling Vega or Arcturus) and being in Pisces, in a region very poor in bright stars, can easily be identified.

Venus is evening star too at her greatest brilliancy appearing about twelve times as bright as Sirius and more than 100 times as bright as Aldebaran She casts a conspicuous shadow If her light is allowed to shine through a window into a darkened room and can be easily seen in the daytime if one knows just where to look Shortly before sunset any one can pick her up, high in the western sky while the Sun is still shining.

At the beginning of March she sets about 9 30 P M and remains in sight until nearly 10 o'clock at the end of the month.

Mars is a morning star in Capricornus, rising about 5 A M Jupiter is likewise a morning star but is further east, in Sagittarius, and rises about 2 15 A M in the middle of the month. Saturn is evening star in

Queer Automobile Bodies

Some Interesting French Designs

THE development of automobiling has been attended by a corresponding development in the construction of automobile bodies, even by an overdevelopment, which has produced queer forms that depart widely from the conventional types although they are not always unpractical or destitute of merit.

Most of these queer looking automobiles are of French make. A well known example is the Grégoire "submarine" which conceals all but the head of the driver. The same firm makes a still more realistic "submarine" which is provided with a conning tower and completely incloses the driver. Then there are cars shaped like artillery shells, with rounded tail pieces in which extra wheels or tires are neatly stowed, and other shell types with glass skylights.

Three novel and bizarre automobile bodies of French make are described and illustrated in the present article taken from the *Allgemeine Automobil Zeitung*. The first is a Turcat-Méry body which is called "The Shark" because it strikingly resembles that fish, especially when seen from in front, owing to the peculiar combination of the lanterns with the mud guards. This constructive device was first suggested in a Napier car which was shown at the last Olympia exhibition in London, and in which the front lanterns were mounted on the ends of the guards. The next development was the mounting of the top lantern on one of the rear mud guards. Finally an ingenious constructor conceived the idea of incorporating the lanterns with, instead of mounting them on the guards. This construction is certainly queer, but it is eminently practical if it is solidly and substantially executed, because the lanterns sharply mark the two extreme front points of the car.

The other two cars herewith illustrated represent two solutions of the problem which many constructors have attacked with more or less success, of producing an open car which can be converted into a closed one without showing at all times the mechanism and the additional parts by which the transformation is effected.

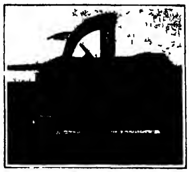
One of these vehicles, the "torpedo" made by Turcat-Méry, is provided with a canvas cover which can be entirely concealed in the body of the open car so that the graceful lines of the torpedo are not marred. This cover affords complete protection and is provided with glass windows.

Still more ingenious is the Phenix officially designated "*Torpedo conduite intérieure Phénix à décapotage complet*," i. e., a torpedo-shaped Phenix car controlled from the inside of a hood which can be made to disappear completely. Two-seated closed cars controlled from the inside are now very popular and in many styles, some of which are very luxurious and costly. The new Phenix car appears to furnish every possible gradation between the completely closed and the entirely open vehicle. It also presents a very graceful appearance, and its lines show originality. The hood is composed of two quarter cylinders, which turn in pivots and can be raised and lowered separately.

The sides of the hood are glazed, and there is a hinged glass window in its convex front. Behind the hood is a disappearing seat for a servant. The front part alone gives sufficient protection against an unpleasant head wind in otherwise agreeable weather. When the front part is dropped a small portion of it remains to form a wind shield of the usual type.

New Phenix car, entirely open.

Hood of new Phenix car, closed.



Hood of new Phenix car, half closed.

Front view of "The Shark."

After part of "The Shark."

"The Shark," so named because the peculiar combination of the lanterns with the mud-guards suggests a monster of the deep.

Treating Table Refuse for Animal Food

A SOMEWHAT original method of securing food for animals from otherwise wasted substances is now being applied in Germany, and it appears to be worthy of note on account of the economy which could thus be secured. At Charlottenburg the city regulations require that all remains of food be placed apart from other household waste, such remains being collected separately each day and taken to a special plant, where they are treated so as to obtain a food product. They are first freed from all non-nutritious matter which is always present, then the material is ground, pressed and dried and finally transformed into a kind of meal which is sold under the name of "bread meal." This is used in the original state or mixed with molasses. It is fairly nutritive but has a large percentage of ash, this being due to the large quantity of bones contained in the waste material. M. Hansen made experiments with the meal in feeding milch cows, and his tests bore upon 76 head divided into three lots, lasting for over three months. The results were encouraging and he considers that the meal should be used alone without mixing with other substances. He brings out the advantages which would be obtained in the way of economy and figures that should such a method be applied in German cities of over 200,000 inhabitants each, totaling 9,000,000 population, the yearly product would be valued at $2,500,000 for stock raising purposes.

Sharpening a Pencil

AN expert manual training man talked with the writer about so simple a thing as sharpening a lead pencil. In the first place, he says, the knife should not be over sharp, but should be a little dull, as if too sharp it will cut quickly through the wood and cut away the lead. If you remember, that is just the way a keen blade will use up a pencil. Then again, he says, it is best to hold the pencil in the left hand with the end to be sharpened pointing away from you and to cut away with a pushing cut, rather than toward you with a drawing cut, as when the point of the pencil is rested against the side of the thumb and is sharpened by a draw cut stroke of the knife blade.

Floating Civic Arts Building

AN interesting and thoroughly modern suggestion is given by a "sketch model of a proposed Civic Arts Building" at the exhibition of the Architectural League, 215 West Fifty-seventh Street. Made to scale it would be a circular building about 450 feet in diameter, with a well proportioned colonnade of early Doric type encircling it, and with a portico at the principal entrance.

This structure, rising abruptly from the water, suggests that the building occupies an island site, but it is in reality upon a buoyant concrete foundation. The foundation has the form of a great double walled bowl with ledges built in amphitheater form on the inner wall on which would be placed regular theater seats. The inner shell of the bowl is a segment of a sphere of smaller radius than the outer one and contacts with it at the lowest point. From this point a dozen or more vertical walls, connecting the two, radiate to the circumference, dividing the intervening space into as many water tight compartments.

This building is proposed as a desirable city enterprise for the maintenance of a civic theater, concert hall, arts and crafts schools, exhibitions and competitions, the discussion of civic public art and other matters—in a word the art and civic center of the people, to be moored at some such accessible point on the water front as Battery Park, where mooring privileges are controlled by the municipality.

The plan creates at no cost a site more desirable than $5,000,000 could secure.

It is the conception of Robert Paine, a sculptor of decided character and originality with a natural affinity for engineering activities, who has several other practical achievements to his credit among which is the sculptor's pointing or enlarging machine.

Proposed floating Civic Arts Building to be moored on the water front.

Rear of the building showing the bowl-shaped buoyant foundation.

Friction of Gas Flow in Pipes

IT is not the intention of this article to impugn the accuracy of the formulæ of Weisbach, Rankine and others with regard to the friction of steam flow in pipes but whether through neglect of the principles laid down by these authorities, or through improper and unintelligent application of them certain it is that there are to-day in what is called "successful operation" many power plants which show on careful analysis of steam meter and other records a loss of power in the piping system which is truly appalling.

A striking illustration of the effects of pipe friction came recently to the writer's attention in the course of some experiments on a medium sized vacuum cleaner such as would be installed in the basement of a forty room dormitory building. Several cleaners of rival makes were being considered, and as all operated on sweeping tests about equally well, it was determined to conduct accurate and thorough tests on each.

With this end in view, a tube of galvanized iron, No. 20 gage, ten feet long and of six inches internal diameter, was fitted at either end with a cone of the same metal, terminating in an opening of 1½ inch internal diameter. Measuring devices being fitted to the cylinder for determining the volume of air delivered to the machine, one of the cone ends was attached directly to the machine, and to the other was coupled ten feet of reinforced rubber suction hose of 1½-inch internal diameter. The end of this latter hose was open and fitted with a coupling to take the various sweeping tools.

The pump being started, the first run was made by detaching this suction hose from the cylinder, in order to get the free delivery volume, velocity, etc. The hose was then attached, with the intention of attaching the various tools to determine their resistance to the admission of air. The pump being again started, with the hose end open, the gage showed about five inches of vacuum when the tube suddenly and completely collapsed, as is shown in the photograph. The iron pipe on which the collapsed tube rests, was later substituted for the latter, and the general arrangements are clearly shown in the cut.

The cause for the collapse of the tin tube could be nothing else than the creation of a vacuum within the cylinder because of the resistance of the ten feet of open hose as the cylinder without the hose withstood the pressure without difficulty. Had the end of the hose been closed in part by the attachment of a sweeping tool, the result might have been expected. Further this collapse was occasioned by the friction of air at comparatively low velocity. To how much greater degree, then must friction be present in pipes through which steam is rushing at high velocity and how especially pronounced must be this effect when it encounters a right angle elbow?

Tin pipe collapsed by vacuum produced by friction of air

The Three-wheeled Tractor

THE vital problem of satisfying the ever increasing demand for trucks of larger capacity has led to the advent of the three-axle tractor trailer method of transportation in which all the propelling mechanism is carried entirely separate from the load-carrying portion. One of the important advantages of this method is the economy in tires and wear and tear of the mechanism. The major portion of the load is not carried on rubber tires but on the steel shod wheels of the trailer which saving alone would pay half the total expense of the largest truck.

A rear wheel drive machine has a tendency to push the front wheels down into the road surface; a front wheel drive pulls the rear wheels up and over. This difference in tendency is so marked that the same power plant, gear ratio and propelling mechanism will give far greater results in speed and pulling ability in a tractor than in a truck.

With a single tractor several trailers may be used, one being delivered while another is being loaded and a third being unloaded, thereby keeping the motor part active all the time; or special unloading trailers may be used in some such lines as coal, ashes, garbage, etc. One dealer having delivered with a chute body ten loads of nine tons each to a distance of three miles, making the enormous total of 270 ton miles for one day. A certain development company uses a twenty yard trailer, receiving a 17 or 20-ton load from a chute and emptying by dumping, each operation taking less than a minute. Such large units are easily handled by using a single steering wheel. The wheel may be turned to at least 80 degrees, pivoting the unit at or near the fifth wheel, the entire vehicle being capable of turning around in a twenty two foot street.

Tractor leaving its trailer to be unloaded while it returns to the coal yard with an "empty"

A Bicycle Automobile

A TWO-WHEEL automobile of unique design has recently been perfected by a western man which differs greatly in its construction from a motorcycle. In fact, the two have little in common. It is like an ordinary automobile with the exception of the number of wheels.

There are two runners under the foot board and when the operator releases his hold on the steering wheel these runners automatically let down on the ground and keep the machine in an upright position. The wind shield is a small oval shaped glass with a convex surface to the wind large enough to protect the driver's face.

The radial frame, rear wheel suspension adds to the comfort of the passenger while an entirely different system of springs is used on the front wheel. The steering knuckles not only turn the wheel but shift the center of gravity making easy steering.

The engine is 3-inch by 4-inch two-cylinder two-cycle valveless type of eight horse-power and an excellent muffler makes silent running.

Although the photograph shows only a one-passenger car, it can be used for two persons by adding a seat over the rear wheel. This is a regular cushioned seat like the front one. One can also adjust a deck over the rear wheel and use the automobile for delivery purposes.

A two-wheeled automobile.

RECENTLY PATENTED INVENTIONS

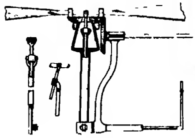
These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Pertaining to Apparel.

HAT.—J. HUTTER, care of Benj. Wertheimer & Co., 656 Broadway, N. Y., N. Y. The object here is to provide a structure which may be readily creased or folded without injury, whereby a hat may be trimmed while in an extended position and then collapsed to take the finished position or the position desired.

Pertaining to Aviation.

FLYING MACHINE.—E. E. PORTER, 808 Realty Bldg., Charlotte, N. C. In this machine the turbine or aerial screw propeller is revolved either horizontally or vertically for the purposes of both supporting and propelling. The construction of the aerial screw propeller by which a single screw is made to do the sup-



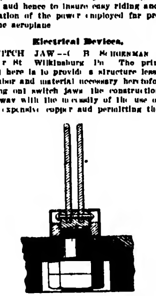
FLYING MACHINE.

porting and propelling consists in automatically oscillating the blades during each revolution and decreasing the pitch in like amount on its opposite side, so that this form of screw has constantly a greater pitch and a greater pull on one side of its rotation than on the opposite side. The screw is thus unbalanced and a sidewise thrust is exerted in addition to and at right angles to the normal thrust of the screw.

AEROPLANE.—H. W. ODLIN, care of Frank T. Burke, Jr., 340 W. 80th St., New York, N. Y. This invention provides an aeroplane arranged to automatically maintain its equilibrium and thus prevent capsizing in heavy winds, or when struck by sudden gusts of wind and hence to insure easy riding and full utilization of the power employed for propelling the aeroplane.

Electrical Devices.

SWITCH JAW.—C. B. SCHOENMAN, 1318 Hunter St., Wilkinsburg, Pa. The principal object here is to provide a structure lessening the labor and material necessary heretofore in turning out switch jaws, the construction doing away with the necessity of the use of the more expensive copper and permitting the use

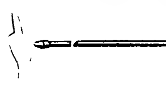


SWITCH JAW

of other metals. The invention relates generally to structures used in electrical work and more particularly to a jaw especially adapted for use with knife switches, fuses and the like.

Of Interest to Farmers.

IMPLEMENT FOR CUTTING AND HANDLING PRICKLY PEAR.—H. H. BROWN, J. O. Box 327, San Antonio, Tex. This invention pertains to implements for clearing the ground



IMPLEMENT FOR CUTTING AND HANDLING PRICKLY PEAR

for purposes of cultivation, the object being to provide an implement which may be easily and quickly handled for the purpose of cutting and handling prickly pear. Broadly the improvement consists in the provision of an implement which embodies a handle and a transversely elongated head at one end of the handle having an outer cutting edge and an engaging prong or tine extending from one side thereof.

BOLL WEEVIL CATCHER.—B. O. HUBBARD, Raymond, Miss. An object of this inventor is to provide a device for catching boll weevils and for simultaneously cultivating the cotton plants, and further to provide a novel form of means for knocking the boll weevil from the cotton plants without injuring the latter.

FRUIT PICKER.—A. H. GILLNESS, Suttons Bay, Mich. In this invention the object is to provide a device for picking fruit which will prevent bruising of the fruit. A further object is to provide a device by means of which fruit

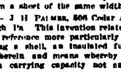
FRUIT PICKER.

in the highest part of the tree may be picked as well as that on the lowest. A further object of the inventor is to provide a device which can be manufactured cheaply for accomplishing the above named results.

Of General Interest.

ENVELOP.—W. F. CROWELL, 39 Wood St., Providence, R. I. The invention provides an envelop made from a sheet of paper of small form width, thus saving paper material in the manufacture of the envelop, dispensing with the use of special dies to form the blanks, and allowing the formation of envelops of different sizes from a sheet of the same width.

FUSE.—J. H. PALMER, 806 Cedar Ave., N. S., Pittsburgh, Pa. This invention relates to fuses and has reference more particularly to a fuse comprising a shell, an insulated fusible conductor therein and means whereby a conductor of a carrying capacity not exceeding a



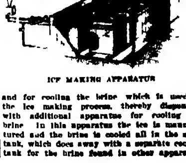
FUSE.

predetermined value can be introduced into the shell. An object is to provide an inexpensive, simple and durable fuse in which the fusible conductor can be easily replaced by a new one of the same carrying capacity or one not exceeding a predeterminate carrying capacity.

CARD INDEX.—D. F. CARVER, 95 Liberty St., New York, N. Y. The main object of this invention is to provide cards with means whereby they will be caused to present themselves in single succession with adjacent cards so spaced apart at the upper edges that at least the heading of each card can be clearly read in succession. The operator is enabled to readily control the cards so as to cause them to be thrown forward in single succession toward the operator each moving forwardly separate and distinct from the one in front and the one behind it.

LENS SYSTEM.—R. D. GRAY, Ridgewood, N. J. This invention relates to photographic objectives and the object is to provide a system more especially designed for use in objectives of telephotographic cameras and arranged to overcome astigmatism, curved field, spherical and chromatic aberration and other defects, such as are frequently found in lenses used in apparatus of this class.

ICE MAKING APPARATUS.—S. R. BELL, 408 Walnut St., Beaumont, Tex. This invention has reference to ice making apparatus, and it has for its purpose the provision of one having combined means for making the ice

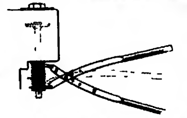


ICE MAKING APPARATUS

and for cooling the brine which is used in the ice making process, thereby dispensing with additional apparatus for cooling the brine. In this apparatus the ice is manufactured and the brine is cooled all in the same tank, which does away with a separate cooling tank for the brine found in other apparatus. The engraving is a perspective view partly in section, showing the ice-making apparatus.

Hardware and Tools.

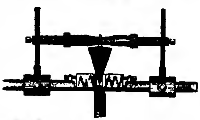
TOOL FOR COMPRESSING VALVE SPRINGS.—C. MYERS, care of Summit & Downee, Huntington, N. Y. In this case the invention pertains to tools for compressing valve springs, and the aim is to provide one with two members, one being disposed in an elongated slot in the other with means by which the two members may be readily pivoted together in adjusted position. Each of the members has a forked terminal disposed at an angle to the body of the member and the members may be readily pivoted together with the



TOOL FOR COMPRESSING VALVE SPRINGS

terminals converging or diverging or if desired the members may be pivoted together with the terminals extended in the same direction and substantially parallel.

REAMER ATTACHMENT FOR DIE STOCKS.—H. BLOOMINGTON, 1609 O'Farrell St., San Francisco, Cal. The invention refers to a reamer attachment for die stocks, and has reference more particularly to a device which comprises an adjustable reamer supporting member adjustably supported on the die stock. The invention provides an inex-



REAMER ATTACHMENT FOR DIE STOCKS

pensive tool which can be easily mounted on any die stock and which will ream the interior extremity of a pipe simultaneously with the threading of the same exteriorly. This improved tool will ream pipes of different sizes without changing the reamer secured thereto.

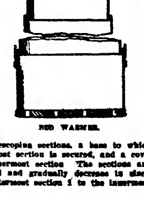
TOOL.—J. STURTEVANT and J. I. WEINZIERL, 1100 3rd Ave., New Kensington, Pa. This invention is more particularly intended for embodiment in detachable handles for cooking utensils, but is capable of embodiment in pliers and other gripping devices. A spring between the crossed handles of a pair of gripping jaws tends to close the jaws, a novel ratchet and spring pawl on the handles hold the jaws in closed position.

Heating and Lighting.

HEATER.—B. COLEMAN, 696 E. 161st St., Bronx, N. Y. This improvement is in heaters applied to a gas fixture in a building to provide a ready and convenient source of heat for rooms and apartments, and it comprises features by means of which the stream of gas that is supplied to the heater is impeded upon entering the same and more evenly distributed to the interior of the heater so as to make the heating effect more efficient and more uniform in practice.

Household Utilities.

BED WARMER.—G. F. SHEPARD, P. O. Box 151, Dodge City, Kan. This invention provides a device by means of which heat may be stored from a suitable source of supply and transferred to the bed warming the bed over an area corresponding to the position occupied by the person using the bed and which while not in use may be stored in a small compass. The invention comprises a plurality of similar



BED WARMER.

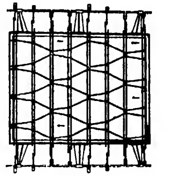
lar telescoping sections, a base to which the outermost section is secured, and a cover for the innermost section. The sections are cylindrical and gradually decrease in size from the outermost section 1 to the innermost section 5, in such manner that the sections fit within one another.

Machines and Mechanical Devices.

RAW STOCK DYEING MACHINE.—S. R. NOAH, Desire Station, Greensboro, N. C. This invention is an improvement in stock dyeing machines, and has for its object the provision of a machine that will take the stock and subject it to a plurality of operations, compressing it after each operation. The device is especially intended for indigo and raw stock.

WIRE STRIPPING MACHINE.—M. PERSIN, 624 E. 13th St., New York, N. Y. The object here is to provide a structure for removing one or more layers of insulation from any desired length of wire. Another object is to provide a structure which will straighten lengths of wire, sever the insulating matter thereon, and then remove the severed portions, each independent part of the insulation being removed to different receptacles.

SINUSOID PROPELLER.—I. J. PADDOCK, Nebraska City, Neb. This invention is based upon the fact that when a flexible surface such as a sheet of fabric, is held at one edge in a current of air or other medium which is traveling in a direction parallel to the normal plane of the sheet, the latter will have imparted to it a series of wave-like motions.



SINUSOID PROPELLER.

These waves follow one another in rapid succession and have the form of a sine curve. Parts of the sheet will be moving upwardly, and other parts will be moving downwardly. An object is to provide a device by means of which the wave-like movements of the sheet may be used for generating power.

AUTOMATIC PUMP.—W. A. HARRIS, 217 John St., Greenville, S. C. This invention relates to improvements in automatic pumps, especially those that are designed to be operated by compressed air. It provides a pump for elevating water which will operate continuously while water is being drawn from a faucet or other outlet, but which will automatically stop after the faucet is closed.

Pertaining to Vehicles.

ATTACHMENT FOR BRAKES.—E. D. SALLTAW, Calhoun, Tenn. This improvement relates to attachments for brakes, and the object is to provide a brake block with two pivoted arms having teeth for engaging and holding the brake shoe in position. The brake block will last indefinitely and the brake shoe may be readily replaced from time to time as required.

Designs.

DESIGN FOR A DRINKING GLASS.—C. HANKS, New Castle, Pa. This ornamental design represents a glass of average elevation in height and curving inward from the top to the middle, thence swelling to the base in very graceful outline. The glass is very neatly embellished with ornamental patterns.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Supplying a Metropolis with Mountain Water

(Concluded from page 208)

when completed, forms the track upon which the forms for the rest of the lining travel The forms are mounted on trucks with wheels tapered to fit the curve of the invert. The forms for the lower half cylinder are practically the same as those for the upper half cylinder After the lining has set the sides of the upper form may be drawn in to free them from the concrete, by operating the turnbuckles *A*, and those of the lower forms by operating the turnbuckles *B* Then jacks may be unscrewed to lower the upper section slightly, freeing it completely from the concrete and jacks *E* may be screwed up to raise the bottom section slightly upon the truck. In this collapsed condition the forms may be drawn forward to complete the next section of tunnel The detail view in the front page drawing shows how the lower forms are supported on the trucks. To the longitudinal beams *C*, vertical guides *D* are bolted, which fit against the framework of the truck The jacks *E* mounted on the truck bear against cross pieces running from *C* to *C* The filling of the lower half of the forms is comparatively simple It is quite a different task, however, to lay the concrete into the upper form Sections of the plating of the upper forms are removed and the concrete is shoveled in adding the plates step by step as necessary, until finally the topmost plate is added when the concrete can be introduced only from the end of the form It will be observed that small pieces of board are temporarily nailed against the edge of the forms and fitted up as neatly as possible against the rock above, so as to retain the concrete until it sets. As each section is completed, grouting holes are left in the top through which, when the lining is completed otherwise grout will be forced under high pressure to fill up all cracks and crevices and make the lining perfectly sound.

At each shaft access will be had to the tunnel through risers or vertical pipes, 48 or 72 inches in diameter At most of the shafts two such pipes will be provided, each fitted with valves at the bottom which may be operated from the surface to close either of them when it is desired to gain access to them or to effect any necessary repairs. The valves at the bottom of the risers will be of such a design as to close automatically in case of an abnormal flow through the risers, due to the destruction of the valve at the top by explosion or other accident. At the top of the risers there will be two valves, the one nearer the riser being an emergency valve, which may be closed in case of any damage to the other valve.

It is probable that no immediate changes will be made in the water supply of Manhattan and Bronx, except that pipe lines will be run from the shafts to help out the existing supply in case of emergency In Brooklyn and Queens, where thirty five pumping stations are now required, most of the stations will be discontinued for the reason that the water will be delivered through the aqueduct at sufficient pressure to reach practically all parts. Only in one or two sections will pumping be necessary

From Hill View reservoir the water will flow through a tunnel, 15 feet in diameter This will be narrowed to 14, 13, 12 and 11 feet, which is the diameter of the rock tunnel at Fort Greene Park, Brooklyn, and at the intersection of Flatbush and Third avenues. From there on steel pipes, five and one half feet in diameter and running down to four feet in diameter will carry the water to the Narrows, and under New York Bay, at the Narrows, the line will be only three feet in diameter This gradual shrinking of the aqueduct reminds one of those large rivers that flow out of the mountains in sufficient volume to be navigable and even a menace to the surrounding country in time of flood, but which, when they reach the deserts are drunk up by the thirsty sands and sucked by the torrid sun until they vanish without any clearly defined terminus or possibly flow in a sickly stream

INQUIRY COLUMN

Inquiry No. 9288. Wanted the names and addresses of concerns that can cast steel balls with pure tin one-sixteenth of an inch thick.

Inquiry No. 9289 Wanted substance melting at 338° and hardening when cold without imparting any flavor to tobacco smoke and without emitting any oil, or fatty vapor

Inquiry No. 9290 Wanted name and address of a manufacturer of a patented device which is suitable for making up pay envelopes, namely, to fold up bills and insert them with minor coins in a pay envelope of the usual size.

Inquiry No. 9291 Want to buy machinery for manufacturing wooden tooth picks.

Inquiry No. 9292 Wanted a gum that will stick labels to grape-fruit.

Inquiry No. 9293. Wanted the names and addresses of manufacturers of waterproof cloth, also samples of such cloth

Inquiry No. 9294. Wanted to buy glass tubing [illegible]

[illegible]

to a small stagnant lagoon. Thus, when the entire Catskill system is completed and operating at its full capacity, the waters which three days before poured out of the Ashokan reservoir in a mighty flood, over seventeen feet in diameter, will reach Staten Island, a stream only 3 per cent of its former size after having been robbed by the rest of the thirsty city

Friedmann's New Tuberculosis Remedy *

By H J Archard, M D.

IT need hardly be said that Dr Friedmann's remedy is not a serum, but a bacterin or vaccine, since it is prepared from tubercle bacilli He admitted the origin of his tubercle bacilli (turtle) under pressure but he refused and still refuses to communicate his method. Although he denies that his tubercle bacilli are originally human, he does not say how he obtained his turtle tubercle bacilli or how he infects the turtles. He denies that he uses the old strain of originally human turtle bacillus with which he worked in Piorkowsky's laboratory some years ago.

If we examine Friedmann's report, what do we find? In his original report, which was published in the *Berliner klinische Wochenschrift* for November 18th, 1912, he describes at length his clinical results in a great variety of tuberculous cases treated with his remedy, by intramuscular and intravenous injection sometimes one or the other, sometimes both simultaneously He asserts that patients show surprising improvement after one or two injections He injects his bacterin into newborn infants, although it contains living tubercle bacilli and says that somewhat over one year after this inoculation not the slightest trace of scrofula or tuberculosis is to be found in any of these children

The account of animal experiments is extremely scant Friedmann avers that his preparation is innocuous for guinea pigs, and that even after years they remain quite healthy Nevertheless, they are not entirely immune to severe artificial infection while his untreated animals succumb to this after about 110 days, guinea pigs immunized with one injection live an average of 201 days. He passes over this comparatively unfavorable result by declaring airily that, fortunately conditions are much more favorable in man since tuberculous infection in human beings is never as severe as artificial infection in guinea pigs.

In the discussion before the *Berliner medizinische Gesellschaft*, which is one of the most searching, most severe, and mostly highly scientific tribunals before which a medical man can come Friedmann's clinical results were confirmed by a number of clinicians, although Blaschko and also Heymann showed only indifferent results in cases of skin tuberculosis and lupus. Citron admits that for treatment and for prophylaxis the use of living germs is correct in principle and was adopted by Jenner and Pasteur, but he insists that great care must be exercised as long as the details of Friedmann's method are not known, he referred to Pasteur's experience with chicken cholera vaccine in which the avirulent virus became virulent and caused destructive epidemics. He says "As long as we do not know the nature of virulence, as long as we are not able to control virulence, but may be confronted at any time with the fact that an avirulent virus has become virulent for some unknown reason, so long we have all been afraid to employ this principle of living virus in man, however much we may agree in principle with Friedmann, that living virus should be employed."

Citron objects to the introduction of an unknown remedy which contains living virus into children who are not clinically tuberculous, although he can find an excuse for the administration of such a rem-

* Abstract of an address opening the discussion on the subject before the North Shore Branch of the Chicago Medical Society, February 4th, 1913.

edy as a last resort in severe tuberculous cases. He warns against the general use of the remedy until Friedmann has clearly stated of what his material consists. He refers to the relatively unfavorable animal experiments, which he calls failures.

Prof Orth reports that the animal experiments did not yield absolutely good results The immunized animals did not live much longer than the control animals. They all acquired tuberculosis.

Felix Klemperer's discussion which was largely historical and along general lines, is immensely interesting but it would lead too far to repeat it, even in abstract He does not believe that *the* curative remedy against tuberculosis has been found, that tuberculosis has been practically eradicated, as was announced by one of the gentlemen in the discussion, but he insists that essential progress has been made He shows the importance of the suppurative action of tuberculin even of Friedmann's turtle tubercle bacilli, which had rendered earlier experiments at immunization futile He asks how Friedmann's remedy has been deprived of this action of producing pus. Klemperer agrees with Citron that prophylactically, i. e for the vaccination of children the use of Friedmann's remedy is rather premature

Goldscheider speaks from the point of view of the practitioner He asserts that the purely clinical improvement which has been described in the cases treated is not sufficient and demands documentary and far better proof than has yet been afforded of the actual benefit derived from the remedy

In the further discussion in which such men as Wolff Eisner Bier and Goldberg took part, similar reasons were advanced for exercising great care and for waiting Schwenk denied that a case of renal tuberculosis which Friedmann had declared to be cured had been improved, in fact he said that the disease was still progressive

When we examine Friedmann's report in detail, we miss first of all the thoroughness and entering into essentials for which Koch's first account of the etiology of tuberculosis has given such a splendid example, and which was followed by other investigators, for instance by Ehrlich in the announcement of his salvarsan Friedmann's account is not satisfactory and must be characterized as empirical far more than scientific At the present day it no longer suffices to say that a remedy has cured or can cure tuberculosis The cure must be established, first by a clinical improvement which may be temporary only and which as a matter of fact has been obtained by other remedies even better than could be done by Friedmann, and has been obtained in this country since 1897, then it must be shown that an actual immunity demonstrable by laboratory tests, by the demonstration of specific antibodies, has been produced, and that this immunity persists for weeks, months, years. It does not appear that Friedmann has made even the simplest serum tests, those for agglutinins, although Koch had shown the way twelve years before and more, and although the behavior of the opsonic curve has been demonstrated conclusively to stand in positive relation to the clinical improvement and to the immunity acquired in the course of treatment

Friedmann's *experimental* proof is pitifully insufficient to establish his contentions. The best he could show was that his experiment animals lived three or four times longer than the controls after virulent infection, while it has been shown with other remedies that experiment animals, notably guinea pigs, absolutely resist a virulent infection to which the controls succumbed in the course of a few months, and that the immunized animals were healthy and free from tuberculosis more than one year after infection.

Although, as pointed out by Citron and other men, the use of living tubercle bacilli is correct in the treatment of tuberculosis in principle, I maintain that the prophylactic use of such material in children and infants is little short of criminal. Friedmann has advanced nothing but his bare assertion that these living tubercle bacilli cannot change in their virulence and become harmful to the children. He can afford no guarantee that he has not infected these children and that eventually they may not acquire a fatal tuberculosis

In spite of all the objections that may be raised against Friedmann's remedy or rather against his administration of it at present, and against his incomplete announcement, I am free to admit that there may be, and probably is, a great deal of good in it We certainly have clinical improvement in a great many cases, which has been confirmed by clinicians and by the physicians in charge We have the disappearance of physical signs the gain in weight the restoration of the working ability the loss of tubercle bacilli in the sputum, even the loss of a positive tuberculin reaction The only question is whether equally good results cannot be obtained with a less questionable because less potentially dangerous remedy This has been done

Dr von Ruck in this country has shown that it is not necessary to inject living tubercle bacilli for the purpose of successful immunization but that a proper combination of the various extractives will accomplish this purpose with equal efficiency and certainly with far greater safety He has even succeeded in removing the suppurative action of the tubercle bacilli by a proper balancing of the content in fats, or perhaps better by removing the excess of fats and waxes from the tubercle bacilli which he had found to be responsible for abscess formation after hypodermic injection

In children who are subjected to prophylactic inoculation with this remedy which, *nota bene*, entails no risk for it does not contain living tubercle bacilli the most surprising clinical improvement was shown especially a decided improvement in nutrition a disappearance of all the clinical signs where they had existed of lung signs of enlarged lymph glands, of anemia, etc and what is more significant the sera of all these children showed a progressive increase in tuberculosis antibodies, agglutinins, amboceptor opsonins Further they showed, and continue to show *lytic power* the power to dissolve tubercle bacilli *in vitro*

The New York Motor Boat Show

THE Motor Boat Show in Madison Square Garden this year was perhaps more than ever chiefly an exhibition of marine engines. There was also a goodly display of boats of various types, though the boats were not so numerous as heretofore The cruisers were represented by two large 40-foot boats, the expensive pleasure craft by a 54-foot Speedway de Visite," having a glass inclosed cabin in the front and a commodious open cockpit in the rear and the speedy runabouts and hydroplanes by a dozen or more boats ranging from 16 to 38 feet in length

As heretofore, the cruisers are fitted with every convenience On account of the high price of gasoline efforts are being made to reduce the fuel consumption to a minimum by means of economical carbureters but there did not seem to be any tendency to use kerosene or crude oil

The hydroplanes, of course, attracted the most attention, especially since they have almost completely taken the place of the displacement type of boat Even that well known builder of steel boats, W H Mullins, has brought out a 16-foot hydroplane hull which, equipped with a 3-cylinder, 2 cycle motor of but 18 to 25 horse-power, is designed to travel at the rate of 28 statute miles an hour, and this all for a moderate price. An ordinary steel launch with inclosed motor in the cockpit can be bought for $300, it is claimed

The hydroplanes were of all types—monoplanes, single-step, and multiple-step. The chief representatives of the second class were the "Baby Reliance II.," winner of one of the three races for the Harmsworth Cup last September, and a new hull, intended to be fitted with two 400 horse-power, 8-cylinder vertical mo-

tors driving twin screws. The multiple-step hydroplane advocated by William H Fauber, was illustrated by 20-foot "Elco-planes" fitted with 150 horse-power and 60 horse-power 8-cylinder and 4-cylinder vertical engines, respectively These boats have made 48.8 miles per hour and 35 miles per hour in tests on Newark Bay Their bottoms are covered with sheet metal having small V-shaped corrugations running lengthwise of the hull, the V's being placed 5 or 6 inches apart. This corrugated metal covering is arranged in 4 and 5 low steps (about an inch) on the low powered and high powered boats, respectively The hull in cross-section forms a wide open V throughout its entire length Longitudinal slots are cut in the vertical sides between the bottom planking and the corrugated sheet metal to let in air and thus keep a vacuum, with its consequent drag, from being produced. The English boat, "Pioneer," which won the international races previously mentioned, was a 5-step Fauber hydroplane. Propelled by two 350 horse-power engines and twin screws she made 43 12 miles per hour in the race as against 42.78 miles per hour scored by the 'Baby Reliance II (fitted with a 150 to 180 horse-power Sterling 8-cylinder 5¼ by 6¾ inch motor) in the race which this boat won

The monoplane type of hydroplane hull in which there is no step, was illustrated by a huge 200 horse-power craft built for an Indianapolis sportsman. A distinctly novel monoplane hull was that of the Viper V,' shown in the basement This hull was just the reverse of the usual hydroplane in that the bottom was deeply concaved from the bow fully half way to the stern—so much so in fact that it is called a sea sled since the sides form what might be called runners. The concavity decreases toward the rear so that the stern is practically flat Twin propellers are mounted on shafts projecting through the vertical stern planking just above the bottom of the boat As only the lower half of the propellers are immersed, they are called surface' propellers. Contrary to the general opinion that a semi submerged propeller is only half as efficient as a totally submerged one, Mr Albert Hickman the designer of this new boat claims that there is only from 6 to 9 per cent slip with surface propellers, while the drag of the shaft, strut, propeller boss, etc (amounting in some cases to 40 per cent of the total resistance) is done away with This boat has outwardly swinging rudder plates hinged to each of its vertical sides. The engine is placed toward the stern instead of in the bow and a generous cockpit is located forward The concave shape of hull is said to be very seaworthy, and also to offer the advantage of trapping the air and forming an air cushion that materially reduces the pounding a hydroplane generally meets with The results obtained with this boat are remarkable A 25 horse-power motor weighing 400 pounds drove a 1,600-pound boat at over 26 miles per hour, while lifting 80 pounds per horse-power This is about four times the efficiency shown by the ordinary hydroplane.

The placing of the motor in a separate compartment in the bow of the boat, which is almost universal this year, makes it difficult to adjust and to start. Consequently either a starting crank is provided in the cockpit or an electric self starting outfit is arranged alongside the motor This latter is a decided improvement, especially where the boat is to be used by ladies, as in addition to the self starting motor, electric lights are provided at night

Achievements and Lessons of the Scott Expedition

IT is, of course, too soon to tell the whole story of what the world has gained through Capt. Robert Scott's second antarctic expedition, in which the heroic leader and four of his companions so cheerfully laid down their lives. The scientific results of his previous expedition (1901 to 1904) filled twelve substantial volumes. It may be years before those of the second expedition are fully

published. Thanks, however, to the journalistic arrangements so admirably worked out in connection with this as with other recent polar enterprises, the salient facts are already before us.

The history of antarctic exploration up to date has comprised two stages. The first extended from the latter part of the eighteenth century to the early years of the twentieth. Some of its great names were Cook, Bellingshausen, Weddell, Balleny, Dumont d'Urville, Wilkes, Ross, Moore, Bruce, Chun, Borchgrevink, Gerlache, Arctowski, Drygalski, Nordenskjold and Charcot. Chronologically this first stage overlaps the second, from which it is distinguished by the fact that its operations were confined almost entirely to the seas surrounding the antarctic continent. Many features of the continent itself were discovered, but nearly always from the decks of vessels, and in many of these discoveries there was a large element of conjecture.

The second stage really took its rise from the meeting of the Sixth International Geographical Congress in London in 1895, when the dissatisfaction of geographers with the previous methods of antarctic research was crystallized in the decision that the actual exploration of the antarctic continent was the most urgent piece of work remaining to be done toward completing our knowledge of the earth's surface; and the means of accomplishing this desideratum were pointed out by Dr. von Neumayer, Sir Joseph Hooker, Sir John Murray and Sir Clements Markham. While special emphasis was given to the work of land expeditions, the continuation of oceanographic research as the wing that throws light upon the nature of the adjacent continent was included in the programme, and the details of the task in hand were thus formulated by Murray:

1. To determine the nature and extent of the antarctic continent.
2. To penetrate into the interior.
3. To ascertain the nature and depth of the ice cap.
4. To observe the character of the underlying rocks and the fossils.
5. To take magnetic and meteorological observations both at sea and on land.
6. To observe the temperature of the ocean at all depths.
7. To take pendulum observations.
8. To sound, trawl and dredge.

To British science belongs the glory of having proved the feasibility and comparative facility of penetrating the ice pack and actually landing parties of explorers on the antarctic continent, and practically all the land journeys in that quarter have been made by Britons, with the exception of Amundsen's. The abortive Japanese undertaking of a year ago hardly deserves mention in this connection, while Filchner's German expedition, expressly organized for the purpose of a long overland journey, appears to have accomplished little if any exploration on land, though the details of his travels just completed are still unknown.

The mere size of Antarctica ought to suggest to the practical reader a number of answers to his inevitable *cui bono?* concerning antarctic exploration in general. The continent of which Capt. Scott in his first expedition was the pioneer explorer covers some five and one half million square miles of the earth's surface—about the area of Europe and Australia combined. A gap of this extent on our maps precludes any complete knowledge of the wind systems of the globe, of the distribution of the magnetic elements, of the main structural features of the earth's crust—in short, of a host of fundamental matters the ultimate practical bearings of which ramify through our everyday life and affect the welfare of all mankind.

Before the new era in South Polar exploration which Scott inaugurated, the continental character of Antarctica was altogether conjectural. It was hardly doubted that at some time in the remote past land had extended continuously from South America to Australia, a fact explaining the remarkable points of resemblance between the existing faunas of those two regions; but all that was known

about the modern remains of this land mass could be explained as well on the assumption of an archipelago masked under a load of ice as upon that of a continent In fact up to a year ago there appeared to be strong reasons for believing that the so-called continent was cleft in twain by a broad channel connecting Ross and Weddell seas and this belief was only conclusively disproved by the combined discoveries of Scott Shackleton and Amundsen

In this place only a hasty summary need be given of the work of Scott's two expeditions which should be considered together since the second was definitely planned as a supplement to the first The first expedition entered Ross Sea which all experience up to date indicates is the most practicable gateway to the interior in January 1902 The first task accomplished was the exploration of the Barrier edge from end to end The Barrier was found to have receded some thirty miles since the days of Ross A landing was made and a captive balloon sent up for the inspection of the interior Next Scott discovered the high land bounding the Barrier to the east and named it King Edward VII Land At the other end of the Barrier he discovered that the volcanoes Erebus and Terror are on an island (Ross Island) and the volcanic formations here were thoroughly studied The great achievement of this expedition however was the exploration of the huge range of mountains extending south from Cape Adair and of the ice plateau lying west of them During the first season Scott made a sledge journey due south parallel to the Victorian range to a point nearly three hundred miles nearer the pole than any one had gone before During the second he traveled westward scaling the mountains by the Ferrar Glacier and advancing over the inland ice one hundred and sixty miles The magnetic observations made on this journey fixed the location of the magnetic pole afterward actually reached by members of Shackleton's expedition During the two years the party made splendid series of meteorological magnetic pendulum tidal and biological observations

The second expedition which sailed in the autumn of 1910 was with the possible exception of Filchner's the strongest scientific expedition that ever entered the Polar regions Shackleton a member of the first expedition had in the meantime returned to the Antarctic on his own account made further explorations from Scott's old base and pushed over the Beardmore Glacier to a new and sensational farthest south in the very heart of the continent Scott's original plan in his second enterprise was to distribute the activities of his large and able staff in four principal directions an eastern party was to explore King Edward Land a western party the Victorian range west of McMurdo Sound a party was to remain at headquarters to carry out elaborate scientific observations and a southern party headed by Scott himself was to proceed if possible to the Pole in order Sir Clements Markham would have us believe to make magnetic observations the only practical reason for going there His expedition as a whole carried out a programme of scientific research as thorough as the most conservative members of the enterprise at home could have desired Some changes in the plans had to be made The eastern party under Lieut Campbell was unable to land on King Edward Land, and proceeded instead to Cape Adair thus becoming the northern party After a year of exploration in that region they were picked up by the expedition ship the Terra Nova and set ashore again at Terra Nova Bay for a short sledge journey The ship was however unable to take them off on account of impassable ice and with very meager stores and only a summer outfit they were obliged to improvise winter quarters in a snowbank, ultimately making their way 200 miles overland to the expedition's base at Cape Evans.

The western party carried out geological work on an extensive scale, and dis-

covered, among other things, a deposit of bituminous coal, evidence that a temperate climate must have once prevailed in this region. They also found thousands of wingless insects of two species. The party at headquarters made very thorough meteorological and magnetic observations. A magnetic observatory was excavated in the side of a glacier to secure uniform temperature throughout the year. The physical work was carried out by Dr. George Simpson of the Indian Meteorological Department, who is a specialist in atmospheric electricity. Dr. Simpson returned to England last summer, and at a meeting of the Royal Meteorological Society announced some very interesting discoveries in meteorological optics made during his southern sojourn. Upper air soundings were made with balloons to a height of six miles. A bold feat carried out in midwinter by Wilson, Bowers and Garrard consisted of a five weeks' journey across the Barrier to study the incubation of the emperor penguins, which breed in winter.

The suggestion made some months ago by Mr. E. S. Balch in the Bulletin of the American Geographical Society that Scott had chosen the meteorologically worst side of the Barrier for his inland route has been tragically confirmed. The furious blizzards for which the whole periphery of the Antarctic continent is notorious, sometimes attaining a force of 70 or 80 miles an hour, appear to be the result of air draining down the slopes of the vast ice-cap of the interior. In accordance with a well known law they are deflected to the left by the rotation of the earth. Thus the furious blizzards of the Barrier are mainly from the south-east, and a glance at the map shows that Scott must have experienced the full brunt of them, to say nothing of the fact that they delayed his departure from his base to a dangerously late period in the season. Amundsen's route, and especially the location of his base, was far more favorable with respect to these winds—and a comparison between his and Scott's experiences affords a striking lesson in antarctic meteorology. However, this comparison does not indicate better judgment on the part of the Norwegian explorer, for his easterly route was chosen solely to avoid trespassing upon territory pre-empted by another.

A comparison between Scott's and Amundsen's methods of travel lies beyond the scope of the present article, but the writer may perhaps be pardoned for suggesting that Scott's preference for human as compared with other modes of traction seems the height of quixotism.

The Heavens in March

(Concluded from page [illegible].)

Taurus setting after 11 P. M. Uranus is in Capricornus, rising about 4 A. M. Neptune is in Gemini, and sets at about 3 A. M.

The Moon is new at 7 P. M. on the 7th, in her first quarter at 4 P. M. on the 15th, full at 7 A. M. on the 22d, and in her last quarter at 8 A. M. on the 29th. She is nearest us on the 21st and farthest away on the 6th. As she completes her circuit of the heavens she passes Jupiter on the 2d, Mars and Uranus on the 4th, Mercury on the 9th, Venus on the 11th, Saturn on the 13th, Neptune on the 17th, Jupiter again on the 29th, and Uranus on the 31st.

At the time of full Moon on the 22d there is a total lunar eclipse. The earlier phases of this are visible in the eastern part of the United States, and the whole eclipse on the Pacific Coast. The Moon goes almost centrally through the Earth's shadow, and totality lasts more than an hour and a half. According to Eastern standard time the first contact of the Moon with the shadow comes at 5 13 A. M., totality lasts from 6 11 to 7 44, and the Moon leaves the shadow at 8 43. Only the beginning of the eclipse can be seen from Washington, but from points on the Pacific Coast, by whose time all the phases occur three hours earlier, the whole eclipse can be observed.

Princeton University Observatory.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12753) C W B. writes In reference to query 12741 please allow me to suggest that there are no hatcheries in the clouds for breeding angle worms toads or frogs. Angle worms breed and live in the ground and they are so secure there that no wind is sufficient to suck them out and up to the clouds. But as their enemies, the birds, prey on them during the daytime, they have become night workers, and parade mostly in the night, and especially during warm rains. The worms P S F saw came out during the "several hours of rain" but a sudden change to snow stiffened them so they could not get back into their holes. They struggled for life and kept on top of the accumulating snow but at last froze to death where he found them Of course, everybody knows that toads and frogs breed in water As soon as they have developed from tadpoles, they generally change their dwelling place from water to land during a warm rain in spring and early summer Their sudden appearance at such times has developed the popular fallacy that they have rained down! Now are not these common sense explanations, and also in accordance with scientific knowledge? A There can be no doubt of the common sense character of C W B s explanation of the phenomenon in question. Nor is there any doubt that in certain storms there is an upward current sufficient to raise small articles and carry them long distances before they drop out of the whirl. Waldo s Elementary Meteorology page 248, states that large rain drops 0.1 inch in diameter require an upward current of only 16 5 miles per hour to sustain them when the air pressure is 23 inches while small rain drops require an air current of only 3 miles per hour to prevent their falling to the ground Also, In case the ascending current in a tornado had a velocity of 100 miles per hour where the pressure of the air is 16 inches, this would prevent a hail stone 2 5 inches in diameter from falling to the ground These ascending currents exist in all violent storms, and in ordinary storms to a lesser degree. Any particular instance must be determined by the circumstances of that particular instance and cannot be determined by any general belief in the possibility or impossibility of the carrying up and dropping of small things from the clouds We grant that this explanation should have been given in the former note so that the meaning might have been clear Our meaning was this Whether small worms were carried up in the particular instance must be determined by a knowledge of the force and character of the storm in question conditions which we did not know The only condition we intended to state was the possibility of such an occurrence with a sufficient rotary motion of the storm.

(12754) J C D asks Please explain in non-technical language how the Chinese use the Chinese abacus to count And why other nations do not use it. A The Chinese abacus is simply a counting board on which the results of computations done in the head are tallied as it were It is a shallow box divided lengthwise by a bar and having several wires crossing the box and passing through the bar On one side of the bar are five balls and on the other side there are two balls. The five balls stand for units, and the two balls stand for five each or ten taken together When the five balls on one wire have been tallied one of the two balls is pushed up the five balls are pushed back and the tally proceeds till another five has been tallied when one on the next wire is pushed up and this ten (or two fives) is pushed down Any wire may be taken as units. Those to the left will be tens hundreds etc those to the right of this will be tenths, hundredths, etc. Simple tallying of calculations is done on the abacus with rapidity, but if a mistake is made it cannot be detected. The work must be gone through again A similar instrument was employed in ancient times by the Romans, but modern nations find paper and pencil a better way to perform their reckoning.

(12755) H J S. writes Recognized as the only authority I seek information. Is it necessary for one to stand on *all* three rails of a third-rail system in order to get a shock? Are not the two running rails connected as one arm of a current, with the third rail as the other? Is it not possible to stand on the third rail and one of the running rails and receive a shock? Also in rain, through a short circuiting, cannot one receive a shock standing on the third rail alone? A In a third-rail system the two rails which carry the cars are in connection with the earth, and cannot give any shock by themselves. The current comes by the third rail from the power house and the third rail is charged to full voltage all the time. Standing on the ground or on one of the rails of the track, you will certainly receive a severe shock by touching the third rail. Standing on the third rail alone, no shock would be felt, since there is no way for the electricity to escape from you to the earth If you step off, you will receive a shock when you put one foot upon the ground, the other being on the third rail.

The purpose of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement

The Proposed New Patent Office Building

On February 15th 1913 Mr Burnett of the House Committee on Public Buildings and Grounds reported a bill on public buildings. Section 15 of this bill authorizes the creation of a commission composed of the Secretary of the Interior the Commissioner of Patents, and the Supervising Architect of the Treasury to cause plans and estimates to be made for a building, to accommodate the United States Patent Office

The President's Commission on Economy and Efficiency in its report of the investigation of the United States Patent Office pointed out the necessity of a new structure in no uncertain terms In the case of the entire force of the office numbering 930 people says the report, it is quite evident that the best results cannot be obtained under existing conditions

The present building was completed in 1867 and the newest wing is now forty five years old While the building was probably adapted to the use to which it was put at the time of construction it is conspicuously unsuited to present needs. The report of the President's Commission points out that the amount of breathing space allowed to employees is most inadequate under the present system of ventilation and that this system cannot be improved because of the large number of persons who are compelled to work in very confined quarters The space consumed in the rooms of the examining divisions is from three to five or more times that found in most offices

The basement floor of the Patent Office is occupied in part as a storeroom Its condition is a disgrace to the Government Dirt conveyed from the streets is deposited on the floors- flag stones between which are large cracks—and accumulates in thick layers on the publications. The condition is aggravated because the sale copies of patents, of which these publications are chiefly composed are open both in front and rear so that the dirt and dust cannot be excluded Much handling of the publications (they are frequently called for) stirs up the dust, so that it seeps into the working rooms of the examiners adjoining the files.

Apart from considerations of health and efficiency, there is the risk of fire There have been two serious fires in the Patent Office in one of which all the original records were destroyed If burned or gutted the record of ownership of the patent property of the whole country would be lost causing irreparable injury to many inventors assignees, and manufacturers While the possibility of loss by fire applies to the Patent Office as a whole it is particularly applicable to the assignment records. The recorded transfers of interests under patents in the United States Patent Office are probably the only recorded evidence of the titles to millions of dollars invested in patent rights

The President's Commission as a result of its investigation recommends that an appropriation be provided for the erection of a new building to be used exclusively by the Patent Office and to be properly designed and equipped The Commission estimates that a suitable building would cost between four and five million dollars, which does not include the cost of site, nor the equipping and furnishing of the building

The House Committee on Public Buildings and Grounds has had under consideration more than seven hundred bills. The total appropriations called for by these measures is more than three hundred million dollars, while the total authorization recommended by the Committee is less than one twelfth of that amount. It is sincerely to be hoped that the Patent Office will not be ignored, and that Mr Burnett's proposals will be accepted by Congress.

Modern Argonauts of Science

An army of scientific workers all over the world is faithfully laboring, and advancing with slow and sure progress the frontier of our knowledge. Research has become systematized, and a gradual widening of our horizon assured. But no systematizing can secure for us the fruits which it is reserved for the great genius to gather The researches of men like Sir J J Thomson, Sir William Ramsay and not a few others stand on a wholly different plane, and must not be compared with the work, however expert, of the rank and file in science Such men do not follow the beaten track, where some degree of success is assured to him who has reasonable skill and sufficient perseverance They achieve that which to the average man would have appeared impossible—until it faces us, an accomplished fact

In the particle shot out by radium with a velocity of 12,000 miles per second, a Ramsay recognizes an atom of helium A Rutherford achieves the incredible task of counting the number of molecules in a measured quantity of gas. A Perrin prepares an "artificial gas" made up of a vast number of particles of nearly equal size thus mimicking the molecules, and furnishing a model which exhibits the characteristic properties of a typical gas. A J J Thomson constructs a miniature gun three inches long and having a bore one two-hundred and fiftieth of an inch, and with it shoots molecules at a muzzle velocity of some ten thousand miles per second He does this to determine their weight, which they are made to register on a photographic plate Is this a fairy story? No, it is far more wonderful than any fairy story, for it is the achievement of man in the twentieth century

What remains for to-morrow to accomplish? We dare not prophesy There are rumors of the synthesis of matter, the building up of molecules from simpler bodies, or perhaps from something which is not matter These rumors may prove unfounded What then? Has not enough been achieved? And the future surely holds a richer harvest still in store

The reader who seeks further information on these things will find it on another page of this issue and in several important articles in this week's Scientific American Supplement

Economy That May Be Disastrous

We have before us a photographic reproduction of a target after it had been fired at by a battleship which used a new system of fire control that enabled the ship to deliver the projectiles of a whole broadside at the enemy simultaneously and practically in the same spot on the ship. Instead of the separate and single shot holes obtained under the present methods of firing this target has huge well-defined gaps ten to twenty feet in diameter, which seem to indicate that a whole salvo of five or ten 13.5-inch shells passed through at those points. Under this system the whole battery is aimed and fired by one man, the errors of individual pointers being eliminated The significance of the result will be the more appreciated when it is known that the firing was not done in smooth water, but in a seaway which caused the firing ship to roll rather heavily

It is a common saying among the officers of our navy that the first salvo which lands will settle the fight—so great will be its moral and material effect. That statement however, refers not to collective, but to individual firing in which such shots of the salvo as landed would be scattered on the ship, whereas the target above referred to proves that one foreign navy, at least has developed a system by which the whole battery of ten or twelve heavy guns can be enabled to bunch its projectiles within a limited area of the enemy's ship.

Now since it will be possible by this system to land at least one such salvo (provided of course that the range were not lost) at intervals of a minute or less, it must be evident to the veriest tyro that the naval battle of the future will be decided not by hours, but by minutes.

In the contest between gun and armor, the victory to-day is decidedly with the gun Our own 14-inch guns can pierce any armor afloat at the present fighting ranges, and already 15- and 16-inch guns are under construction for some foreign navies. In spite of their exceedingly heavy armor, not even our own "Pennsylvania" and "Nevada" could withstand such an attack as was successfully delivered in the case of the target practice above referred to. One single concentrated broadside might easily disable her, and it would not take many such to send her to the bottom.

It is certain that among the leading powers there is no element of naval efficiency to which so much thought, attention and practice is given as that of good shooting. No one navy will have any monopoly of this. It is reasonable and prudent to suppose that, if our battleships ever find themselves drawn up in line against those of an enemy, the shooting of the foe will be just as good as our own. If this system of one-man control of the fire becomes general, as it must do in the course of time, it is evident that victory will belong to that fleet which is able to place the greatest number of heavy guns along the battle line. In the future battleship fight Providence will certainly be on the side of the heaviest artillery, and a preponderance in ships and guns will probably spell an early victory for the fleet that has it.

The Scientific American is to-day, as it has always been, a most earnest advocate of peaceful methods—where they are possible We are strongly in sympathy with the efforts which have been made to bring about universal arbitration At the same time we believe that one of the strongest influences making for peace, particularly in the case of this country, is the possession of a navy sufficiently strong to cope with any international emergencies which may arise. Do we possess such a fleet? We do not, and that our navy is far below the strength which it should have, and is in danger (if the present small navy policy is followed) of falling yet more below that standard, is evident from the following comparison of our strength with that of the two most powerful foreign navies (except, of course, that of Great Britain) in the two oceans.

If Congress makes appropriation for one battleship only this year the vessel may possibly be in commission by the year 1916, and if so, a comparison of our battleship and battle-cruiser strength with that of Japan and Germany shows the following results

Assuming that the battle-cruisers, as their name suggests, will be put into the battle line of a great engagement, we find that in the year 1916 Japan will be able to oppose to our ten dreadnought battleships six battleships and seven of the largest battle-cruisers, making thirteen vessels well armored and carrying the heaviest guns, and that Germany can oppose eight armored cruisers and seventeen battleships against our ten battleships Of battle-cruisers we do not possess any Now assuming that the one-man control of fire has become general by that year, and that the first five or ten minutes of an engagement will probably decide the issues of the fight, it is seen that Japan would have a superiority at the outset of 30 per cent in ships, while Germany would be in a position to oppose a first fighting line of thirteen ships to our ten, with a reserve of twelve first-class ships to relieve their first line, should it be badly punished or, what is more probable, to engage our fleet simultaneously on the other broadside

In the presence of these facts we ask On what possible theory of patriotic and far-sighted statesmanship, is the House of Representatives proceeding in its present opposition to the demands of the country for an adequate navy?

The Money Value of Street Lighting

The most prosperous, the most talked-of street in the western hemisphere is Broadway, New York Electric lighting made it so. Its millions of electric bulbs stand for business enterprise, wealth, prosperity That good street lighting means dollars and cents to a community, the city of Cleveland has demonstrated to its own satisfaction. A few years ago the north side of Euclid Avenue, between East Fifty fifth and East Sixty-sixth streets, installed a block of ornamental street fixtures. The result was magical. That side of the street was crowded, the other side, deserted. Real estate values increased on the illuminated and decreased on the dark side. Not until both sides were equally well lighted was a commercial equilibrium established on that particular section of Euclid Avenue Similarly, Minnesota Street, between Fourth and Seventh streets, in St Paul, was transformed from a gloomy thoroughfare, flanked by dilapidated structures, into a prosperous street in which new buildings took the place of the old—a result accomplished entirely by street lighting.

Three hundred cities in the United States and Canada have tried ornamental street lighting and have found that it pays as a municipal investment, as well as in heightened civic pride, in greater prestige, and, therefore, in better citizenship.

Cities, like human beings, are judged by impressions. The fleeting glimpse of a town caught from the windows of a railway train that stops for a few minutes at a station leaves an indelible impression upon the traveler If he sees nothing but forbidding gloom, punctuated by an occasional flickering gas lamp, he inevitably sets down that community as a third-rate municipality, if he catches a glimpse of a main street ablaze with light, he knows that here business thrives. Gloom means dirt, squalor, stagnation; light means activity, industry, life. From the lighting of a city its character can invariably be deduced.

Electricity

The Largest Swiss Hydro-electric Generating Station.—The hydro-electric generating station which is now being equipped at Laufenburg, on the Rhine, for completion in 1914, will be the largest plant of its kind in Switzerland. The ten turbines will have an aggregate capacity of 32,000 kilowatts, at 6,000 volts which will be stepped up to 47,000 volts for transmission. It is estimated that Swiss waters are capable of furnishing two million horse-power of which upward of one half million horse-power is now "harnessed" and in actual use.

A Novel Ice-breaker.—A high-tension wire in the spray above a dam recently became so loaded with ice as to stretch and sag until it was down almost to the water. Ice hung upon it in a sheet like an apron, thickest in the middle like a thin crescent moon. A power-house employee suggested shooting it off with small shot which could not injure the wire. Standing some distance below, so that the shot scattered widely, he broke off the ice in sections of two or three feet until the wire was entirely clean.

Further Improvement in the Steam Turbine-generator.—A distinguished British electrical engineer announces some very promising experiments in obtaining higher efficiency for the steam turbine, so increasingly employed in electric generating plants. The new method consists in re-superheating the steam after it has passed through one of the stages of the turbine and using high temperature, the latter being rendered possible by coating the steel blading with sheet nickel. A 5,000-kilowatt steam-turbine generator on this system was found to consume only 7 pounds of steam per shaft horse-power, and a still better performance is expected, namely, 6 pounds of steam per horse-power, or a thermal efficiency of 24 per cent.

Submarine Telephony Over Uninsulated Cables.—It is reported that telephoning over a bare iron submarine cable has been accomplished by the invention of an Englishman. Using ordinary telephone apparatus clear-speech transmission was obtained, and even the loud-speaking reproduction of a phonograph record, over eleven miles of this uninsulated cable. From present advices it appears that a thin layer of hydrogen on the surface of the immersed conductor, supplied electrolytically by a polarizing or "pilot" current performs the function of the usual dielectric—certainly an ideally cheap insulation. Another advantage claimed is the elimination of electrostatic capacity—a very important point where long-distance submarine telephony is concerned.

Electric Power from Coke-oven Gases.—Internal combustion engines utilizing furnace gases are increasingly employed in Europe. A large mining and metallurgical works in the north of France has decided to use the gas from 160 recently-built coke furnaces to obtain power for operating electric motors and lights about the works and in the surrounding district. Two methods of developing power from gas fuel are to be used. Burning the gas under steam boilers, which in turn supply steam-turbine generators, and piping the gas direct to internal-combustion engines. When completed the latter plant will consist of six generator units each of 12,000-kilowatts capacity. A gas holder of 15,000 cubic feet capacity will serve to tide over any temporary failure of the gas supply.

International Transmission Line.—The new power line which runs for 85 miles from the Swiss hydraulic plant of Olten-Goesgen in order to bring current to the extensive Ronchamp coal mines in east France is of interest from the fact that it crosses three countries, that is, Switzerland, Germany (Alsace) and France. It is also a good example of the modern use of current for lighting and motors in coal mines and this is in fact on the increase in Europe. The present mines are located in the coal district near Belfort and not far from the German frontier. About 6,000 horse-power in the shape of three-phase current will be brought over the pole line, using 70,000 volts. High steel towers are a noteworthy feature of the line, and the span is an unusually long one of 650 feet.

Lighting Light-Buoys by Wireless.—A German inventor Grimmeisen claims to have found a method for using wireless waves in the best manner for lighting up distant lamps, either electric or gas lamps, by the use of an accurately tuned wireless receiver at each lamp so that it is sensitive to only one wave pitch and no others. The wireless waves act upon a receiver combined with a local relay for working an electromagnetic switch so as to turn on the current or gas as the case may be. This idea is in itself not a new one, as we are already familiar with wireless-distant control devices, but the originality lies in the close tuning of the receivers so that only a given wave frequency will work them. The device will thus be a valuable one for seacoast lights, and especially for light buoys. Before this, sea cables were run from the buoys to shore to bring the current, but such cables need to be very strong so as to stand the severe strain of the waves. On the new plan, a battery can be used in the buoy, and the current be turned on by wireless.

Science

An Iceberg Patrol.—In accordance with an agreement between the British government and the North Atlantic steamship lines, the British Board of Trade is fitting out a ship to patrol the steamship routes in search of icebergs and other dangers to navigation. The vessel engaged for this purpose is the "Scotia," known to fame as the ship of the Scottish Antarctic Expedition of 1902 to 1904. She was originally a Norwegian whaler, the "Hekla."

To Explore New Guinea in an Airship.—Lieut. Graetz, the German traveler who gained fame by crossing Africa first in a motor-car and then in a motor-boat, is now trying to finance a scheme for sailing over New Guinea in an airship for the purpose of exploring the little-known interior of that island. The proposal has been well received in Germany. A similar plan for exploring New Guinea was proposed two or three years ago by Dr. Kurt Wegener, but never came to anything.

Fixing India Ink.—The composition of India ink—a mixture of ivory-black and a colloidal substance such as fish-glue causes drawings, diagrams or designs made with it to run and blur when wet or even dampened by the moisture of the air. This is a serious disadvantage in many cases, especially for industrial purposes. *Les Annales* suggests a remedy which makes the ink practically indelible. This is to brush the design when made with a solution of 20 grammes of potassium bichromate and 20 grammes of bichromate of ammonia in 100 grammes of water.

An International Phytogeographical Excursion Across the United States—evidently inspired by the great success of transcontinental geographic tour of last summer—is now being organized, a preliminary announcement on the subject having been issued by Prof. H. C. Cowles of the University of Chicago, and Prof. F. E. Clements of the University of Minnesota. The excursion is to begin at Chicago about August 1st, and close at New York about October 5th, 1913. Well-known typical forms of vegetation will be inspected along the route, and several universities and other institutions of botanical interest will be visited.

The New French Chronology.—The use of the new 24-hour time system in France is likely to give rise to some rather curious results. One of these is brought out by A. De Mortillet and relates to the striking of the hour. It will not be very practical to use 24 strokes or less in succession as these would be very difficult to count after a certain point. The number of strokes should therefore be reduced in some way. He proposes using a double chime, one bell for units and the second for tens, the two bells to have a different tone. Or else with a single bell rapid strokes would show the tens, and slow strokes the units. With two bells, one bell gives strokes up to 9. The second bell rings once for 10. For 11, the first bell rings once and the second once, and so on in the decimal system. For 20, the first bell rings twice, and so on.

Tellier at Last Recognized.—At the age of eighty-five years and living almost in penury Charles Tellier the inventor of the system of cold storage now used all over the world was decorated recently with the cross of the Legion of Honor, and banqueted by the International Cold Storage Association. A subscription of \$15,000 was raised for him, so that the remaining years of his life may be passed in comfort. Like many another inventor before him he sacrificed everything in carrying out a brilliant idea. As early as 1876 he built the ship La Frigorifique" which took a cargo of frozen meat from Rouen to La Plata, the first consignment of what has since become an industry of world-wide trade. Fittingly enough the banquet given in Tellier's honor was composed exclusively of products from distant countries the transport of which was made possible by the method suggested over a generation ago by Tellier.

The Tsangpo-Brahmaputra Question.—At this late date, when cartographers have generally ceased to indicate their doubts about the identity of the Tsangpo and the Brahmaputra rivers by the use of a dotted line in the unexplored section, it is rather disconcerting to have the old question raised at a meeting of the Royal Geographical Society, as happened a few weeks ago. In discussing a report by Mr. Bentinck on the geographical results of the Abor expedition, Capt. L. A. Bethell, who spent some time near the Tsangpo during the Lhasa expedition and who has recently been stationed along the Dihong (the supposed connecting link between the Tsangpo and the Brahmaputra), expressed his belief that the Dihong has not the volume of water that it ought to have if it were continuous with the Tsangpo. He observed moreover, that the Dihong was extremely sensitive to local conditions of rainfall, and behaved exactly as it would if entirely dependent for its water on a local catchment basin. Fortunately there is a British expedition working along the Dihong this winter, and if it is merely a local stream this fact will probably be ascertained. But, if so, where is the outlet of the Tsangpo, the greatest river of Tibet? It is truly exasperating that explorers are not able to traverse some fifty or sixty miles of debatable ground on the Tibetan frontier and settle once for all one of the most interesting of geographical problems.

Aeronautics

An Aeroplane Boat.—Shakir S. Jerwan and Fuad S. Jerwan of New York city have patented, No. 1,049,865, an aeromotor boat which has an aeroplane with wing frames and a tail frame from which means are supported to float upon the surface of a body of water to buoy up the aeroplane and comprising air tanks supported beneath the wing frames and the tail frame to prevent them from dipping into the water.

A Wright Patent Decision in America.—On the 27th ult. by a decision handed down by Judge Hazel of the United States District Court, the Herring-Curtiss Company and Glenn H. Curtiss individually, are held to infringe the Wright patent. While the Curtiss machine differs in form from the Wright the court held the use of ailerons and a vertical rudder was the same in principle as warping wings and said rudder especially since Curtiss often uses the rudder to help right the aeroplane when it tips. The text of the decision will be published in the SCIENTIFIC AMERICAN.

Wright Patents Upheld in Germany.—A judgment rendered in the Supreme Court of the German Empire on the 26th of February appears to have upheld the Wright patent. By this decision the invalidating of the basic feature of the Wright patent—the warping of the wings in conjunction with the movement of the vertical rudder—by the German Patent Office, does not stand. The only reason the court did not allow the warping of the wings alone was on account of the publication of this principle by the Wrights and Chanute prior to the application for letters patent.

A Record Flight from Paris to London.—On the 25th ult. a new record of 1 hours and 5 minutes was made for the 300-mile flight from Paris to London by the French aviator M. G. Brindejonc des Moulinais. Starting from Paris at 9.15 A. M. a descent was made at Calais 1 hour and 35 minutes later. The flight across the channel was made in a fog and the aviator finally reached the outskirts of London at 1.30 P. M. An average speed of over 90 miles per hour seems to have been attained by the high-powered Morane-Saulnier monoplane.

A Safety Harness for Aviators.—In order to harness an aviator to the machine and at the same time permit him to readily release himself when desired, Willard Irving Twombly of New York city has secured a patent, No. 1,050,874, for a safety harness in which a series of straps are connected together at one end and to the framework of an aeroplane and extend over the shoulders and around the body of the aviator and means are provided for assembling all of the free ends of the straps in front of the aviator, so that he can simultaneously release them, when desired.

A Successful Trans-Alpine Flight.—For the second time a monoplane has flown across the Alps from Brigue to Domodossola. Jean Bielovucic, a young fellow countryman of Chavez, whose first flight across on September 25th, 1910, terminated fatally in the second to accomplish this feat, and to make the flight in mid-winter at that. Besides paper clothes, he wore three thick jackets and woolen gloves. His machine was a Hanriot monoplane. The start was made from a plateau near Brigue from which the snow had been cleared, at noon on January 25th. The weather was fine there being little or no wind. In a few minutes the machine had risen to a height of 7,500 feet and it disappeared from view. Profiting by Chavez's experience Bielovucic flew over the Monteera Pass where the air-whirls and gusts are not so dangerous as over the Simplon. In 28 minutes he was above Domodossola where he volplaned safely to earth. He reached an elevation of 2,800 meters (9,180 feet) during the flight. His chief sensation was a feeling of loneliness when high above the Pass. Upon alighting he was rather light-headed and numb with the cold.

Latest Requirements for Army Aeroplanes.—Specifications which have lately been issued for army aeroplanes are not nearly as rigid and difficult of fulfilment as they doubtless would be if the aeronautic industry in America had kept pace with that abroad. The new machines must be capable of a speed of from 38 to 55 miles per hour. They must carry two persons and a radio-telegraph set weighing about 75 pounds. They must ascend 2,000 feet in 10 minutes when carrying a live load of 450 pounds, and must make a continuous flight of 4 hours duration during the first part of which a flight of 180 miles across country must be included. All new army aeroplanes must be capable of arising from or alighting upon a harrowed field or a field covered with long grass in not over 100 yards. They must describe figure 8s within a rectangle 500 yards by 200 yards without losing more than 100 feet in altitude. The aviator may make this test alone. A higher rating will be given machines provided with an efficient stabilizing device, a motor that can be started from within the body and a motor having an effective muffler with cut-out, also a flight in a 20-mile wind will add to the rating. All machines must have bodies protected with chrome sheet steel 0.075 inch thick.

Salt-rising Bread

Raising Dough With Newly Discovered Bacteria

By H A Kohman, Senior Fellow of Bread Research, University of Pittsburgh

[THE author holds a fellowship granted by the National Association of Master Bakers for Research on the Chemistry of Bread, under the direction of Prof Robert Kennedy Duncan EDITOR.]

The history of bread extends over incalculable time, and its origin is quite obscured in the mists of antiquity The words 'bread and leaven' receive mention in Genesis and Exodus and other books of the Old Testament indicating that baking as an art was practised in remote ages The early discovery of the leaven process was without a doubt purely accidental and may be traced to the fact that in eastern countries a mixture of meal and water if forgotten for a day will ferment This simple way of inciting fermentation together with the advantages of light bread soon led to the adoption of the leaven process

Although leaven was used even in ancient times, bread making methods remained crude and uncertain and the nature of fermentation was not understood until recent years. It was the classic work of Pasteur in 1857 that proved beyond any reasonable doubt, that alcoholic fermentation, such as occurs in ordinary bread owes its origin to one-celled, microscopic plants (yeasts) As the result of this research and others, the manufacture of yeast has become a science and the old time leaven has been replaced by the almost perfect product now available Naturally the progress in yeast making was followed by revolutions in baking Yeast has proved to be literally the life of the baking business, and has made it one of the world's great industries

While the method of preparing bread with yeast has been extensively investigated and the function of this micro-organism in bread is thoroughly understood salt rising bread has been peculiarly neglected If we search the literature upon bread, we shall find volumes upon its preparation by means of yeast—and a mere smattering upon salt rising methods. Yeast bread is made upon scientific principles but the methods for the salt rising type are as crude and uncertain as they were centuries ago' The housewife and the baker still rely upon the old fashioned 'emptins' and to them it is a matter of speculation why these so often fail to rise. Yet with many people salt rising bread is the favorite bread Ex Governor Stubbs of Kansas is intensely fond of it and praises its strength giving powers. He is so fond of this bread that he induced his daughter to learn to make it by promising her a valuable prize should success crown her efforts. At first she met with frequent failures, and at times was compelled to throw a batch out to the chickens.

There is no consensus of opinion in the literature upon salt rising bread Most of the writers maintain that the gas formation which aerates this bread owes its origin to wild yeasts that accidentally get into the batch from the air or ingredients used Necessarily then it is a matter of chance as to whether the bread will or will not rise, and, indeed failures are not uncommon Some writers speak of a spontaneous fermentation and ferments, but do not specify what the germs are.

With the view of putting the preparation of salt rising bread upon a scientific basis, a thorough investigation was undertaken in the Department of Industrial Research in the University of Kansas, and completed in a similar department in the University of Pittsburgh In this investigation surprisingly interesting results were obtained A microscopic study of the 'emptins' revealed the fact that it is not yeast at all, as has been maintained but certain bacteria that raise this bread From the teeming flora of bacteria that occur in salt rising dough it was possible, with extreme difficulty and after many failures, to isolate a bacillus, which by itself can be used in making salt rising bread Not only was this bacillus tried in the laboratory, but in the home and bakery as well. A number of housewives used it with continued success, and in a modern, up-to-date bakery, where failures had been frequent, a month's trial gave perfect uniformity of bread from day to day As the discovery of yeast by Pasteur led to revolutions in the manufacture of yeast and bread making, it does not seem unlikely that the discovery of this bacillus, which is an exact parallel, will revolutionize the manufacture of salt rising bread

Section of salt-rising bread.

A double loaf of salt-rising bread.

The bread research laboratory at the University of Kansas.

The idea of making bread with bacteria need seem neither dangerous nor distasteful A bacillus may be more dangerous than a bullet," but not necessarily so. There are good ones and bad ones. Each species is specific in its action. They cause our most dreaded diseases, it is true, but they also make our vinegar, ripen our cheese, flavor our butter and tobacco, and hence no objection can be made to their raising our bread How does this bacillus differ from yeast? Each consists of small, microscopic cells that must be magnified many times to be visible. Yeast cells are oval shaped bodies, while the salt rising bacillus is rod shaped The cells of either are independent plants capable of life and reproduction. Yeast multiplies by a process of budding, while the bacilli reproduce by a division of cells known as fission " hence the many fission fungi. Reproduction proceeds with surprising rapidity, a cell dividing about every eighteen minutes. From this geometric ratio it has been carefully calculated that if there were sufficient culture media, and growth were not curtailed by prohibitive by products, the progeny of a single cell would, within a week, literally fill the oceans.

Chemically, this bacillus is easily distinguished from yeast. Yeast, as every one knows, decomposes sugar into carbon dioxide and alcohol, the former of which owing to its gaseous nature, aerates the bread Curiously enough, the same chemical changes that aerate bread take place in the production of all alcoholic liquors. The salt rising bacillus produces no alcohol, and the gas, instead of consisting totally of carbon dioxide, is two thirds hydrogen and one third carbon dioxide Hydrogen is a very light, combustible gas, and in equal quantities will aerate twenty-two times as much bread as carbon dioxide Owing to its rarity, hydrogen possesses great buoyancy, in consequence of which it is used in filling balloons and dirigibles. It must not be inferred, however, that the lightness of the gas makes proportionally lighter bread As a matter of fact salt rising bread is distinctly solid and close grained, resembling more nearly home-made bread than bakers bread.

The low density of the gases produced by the salt rising bacillus, coupled with the fact that no alcohol is produced, has an interesting economic significance Scientific research has demonstrated beyond doubt that during the normal fermentation and baking of bread, appreciable losses occur These losses, which have been estimated to approximate four or five per cent of the total nutrient value of the bread owe their origin largely to the production of alcohol and carbon dioxide, both of which, on account of their volatility, are lost In salt rising bread, these losses are less than one per cent In consequence of this difference, salt rising bread is richer and sweeter than yeast bread, for the formation of alcohol and carbon dioxide signify consumption of sugar This difference of three or four per cent in the bread yield seems a trifling matter when calculated on a bag of flour, but in the aggregate it sums up to a surprising consideration. Calculated on the Kansas wheat crop, for example, the possible saving is sufficient to cover the maintenance of both the university and the agricultural college.

The microbic flora in salt rising bread may vary greatly Frequently *Bacillus coli communis* occurs in great numbers in the mass of fermenting dough. This organism, as you know, because of its association with typhoid and other disease germs, renders water unfit for use. Yet the occurrence of this bacillus in bread is no cause for alarm, for it perishes in the oven. Furthermore, there is a sure way to prevent its ever occurring Whenever the liquid used in setting the "emptins" is brought to a boil, *Bacillus coli communis* will never appear, for it does not form spores and hence perishes in boiling water The salt rising bacillus discovered through these experiments, on the other hand, because of its sporulation, withstands this treatment. In the bread, however, even this bacillus, being in the sensitive vegetative state, always perishes in the oven. Hence, salt-rising bread is as sterile as bread made with yeast.

Why eat salt-rising bread? This is a perfectly nat-

A New Method of Educating Deaf Mutes

By Jacques Boyer

DR. MARAGE, celebrated for his many researches on the vocal and auditory organs, describes, in a communication presented to the Paris Academy of Sciences on January 13th, 1913, the principles of a new method of educating deaf mutes. Several years ago,[1] Dr. Marage showed how the auditory faculty of deaf mutes and other deaf persons can be educated with the aid of a novel siren of his invention. In nearly every case he succeeded in causing the pupil to hear very simple vibrations, as a child learns the letters of the alphabet before he attempts to analyse words and phrases.

But the vibrations employed to reproduce the vowel sounds *OU*, *O*, *A*, *E*, *I* (those of the English words *boot*, *on*, *ah*, *get*, *feet*) although differing in duration, pitch and intensity, were alike in form, quality or *timbre*. The pupil, having caught a vowel sound produced by the siren under a certain pressure endeavored to repeat that sound.

Dr. Marage has undertaken to complete his method by an appropriate training of the enfeebled auditory faculty in the perception of the more complex vibrations of speech. These vibrations (apart from the consonants, or supra-laryngeal noises, which begin and terminate the vowels) consist of the vowel sounds modified by superposed vibrations, which represent the *timbre* of the individual voice and the defects in pronunciation.

In order to obtain the variation of *timbre* required for the application of his method of progressive education of the ear, Dr. Marage causes the notes emitted by the siren, before they reach the pupil's ear, to traverse one of a series of buccal resonators, which are casts of the human mouth in the positions which it assumes in pronouncing the various vowels. The *timbre* of the note produced by the siren thus modified varies with the pitch.

These variations can be traced in the records of vibrations which are shown in connection with the accompanying photograph of the siren. The first record (on the left) was made by vowel *A* emitted by the siren without the resonator. The pitch was gradually lowered from beginning to end of the emission (from top to bottom of the record), but the vibrations preserve their original form, although they increase in intensity.

The second record was made with the same siren, emitting the vowel *A* with gradually lowered pitch, but the buccal resonator corresponding to the vowel *O* was interposed in the path of the sound. The trace of the vibrations varies continually in form and becomes more complex as the pitch is lowered.

The third record, made in the same way with the *OU* resonator attached to the *A* siren shows still greater variations. In each case the sound heard is the vowel *A* more or less modified, as if it were uttered by a poor speaker. With this apparatus and the various buccal resonators, therefore, it is possible to vary at will the four essential characters of the sound: pitch, duration, intensity and quality or *timbre*.

According to Dr. Marage, the auditory education of deaf mutes or the re-education of persons who have become deaf, requires the employment of aerial vibrations, such as those which the siren produces, in preference to the vibrations of metal rods or other instruments. The vibrations, furthermore, should be well known through preliminary photographic registration. The training should commence with very simple vibrations of constant *timbre*, representing the fundamental tones of the vowels, and should extend gradually to the more complex vibrations of variable *timbre* which occur in natural speech, the intensity of the sounds being varied from week to week in order to test the improvement in acuteness of hearing. In this way the auditory centers are awakened and the pupil gradually becomes able to understand ordinary conversation.

Emerging from behind another vehicle, the driver can observe vehicles coming from the opposite direction and avoid possible collision.

Left Side Steer and Center Control in Motor Cars

By Howard Greene

WHEN automobiles first rolled on their uncertain and spasmodic ways over the roads that for so long had been sacred to the horse, they were built after a fashion that gave them every right to the appellation "horseless carriages." In truth they were nothing else, for the simple reason that, modeled after the only type of vehicle that was available as a pattern, they perforce embodied about as many of the characteristics of the horse vehicle as were not absolutely unnecessary in mechanical locomotion. What could be more natural, among other things, than that the driver should sit on the right hand side of the machine, just as the driver always had sat on the right hand side of the carriage? It was a thing accepted without question and probably without thought—so much as a matter of course that only within the last few years has there been anything like a general appreciation of the fact that there are very good reasons why the chauffeur should steer from the left side of the car. Now, however, there are many cars in which left hand steer and center control are standard, and the tendency toward this arrangement of control is becoming unmistakably stronger.

There are disadvantages in right side steering that are of considerably more importance than might appear to be the case on first thought. When, for example, a car draws up to a curb in the way prescribed by law—that is, with the right hand side of the car next to the sidewalk—a passenger sitting to the left of the chauffeur must get out into the road and walk around the machine in order to reach the sidewalk. In nine cases out of ten he cannot get out on the right hand side because he cannot pass the chauffeur and the steering wheel, and the chauffeur cannot pass the control levers. If the road is muddy or dusty the short walk around the car may be a very unpleasant one and, moreover, there is a certain element of danger from passing vehicles, to say nothing of the possibility of being splashed with mud or enveloped in dust from their wheels. The chauffeur is no better off in this respect than the passenger in the front seat, for except in the few cases where he can wriggle out between the levers he must ask the passenger to get out of his way or else climb over him. On the road with the car in rapid motion there is a phase of the right side steering situation that is more serious in that it involves more than mere discomfort. In meeting other vehicles, often also moving rapidly, it not infrequently happens that there is very little room to spare. The car may be in a street crowded with vehicular traffic or on a narrow country road where there is little opportunity to turn out. The chauffeur sits on the right, however, where he is in the worst possible position to see just how many inches there are between the wheels of his car and those of the other vehicle. Obviously an error of judgment is much more easily made where the chauffeur cannot see than where he can, and there is the possibility that both drivers may err.

It is argued in favor of right side steering that it is easy for the chauffeur to see just what he is doing when pulling up to a curb, and also that the right side position is the best when overtaking other vehicles on the road—all of which is more or less true. The ready rejoinder is, however, that experience has shown that there is little or no difficulty in making a good approach to a curb steering from the left side after a little practice, especially as the curb is stationary and there is no particular necessity for speed. And when overtaking other vehicles on the road no wise driver will speed up his car if there is so little room to spare that great accuracy of judgment is necessitated; usually the conditions are such that the overtaking car can choose the time for getting by, and so avoid complications. And in any case judging distance on the right

Guns for Submarines

A Weapon That Swings Below Decks During Submergence

By Dr. Alfred Gradenwitz

Submarine gun at high-angle fire practice.

PRESENT tendencies in the construction of submarine boats are mainly toward an increase of their displacement Moreover in addition to the torpedoes carried in such boats, it is now thought advisable to equip them with defensive and protective ordnance

In accordance with the special purposes of submarine boats, Messrs Krupp have in this connection developed some special types of ordnance In order to reduce as far as possible the water resistance in traveling below the surface tapering-carriage guns of non rusting, nickel steel were chosen in the case of small calibers As regards, on the other hand medium caliber guns, which on account of their size, would oppose a considerable resistance to the water thus reducing materially the speed of traveling means had to be provided for the ordnance to be stowed away during protracted voyages below the surface These guns are designed for being got into fighting order with a few manipulations and in a minimum of time, after emerging from the water A condition to be complied with in both cases then was to make any sensitive or disturbing parts (breech sights, shoulder rests etc) readily attachable and removable

We present views of a gun of 7 5 centimeters caliber which comprises a pivoting carriage calculated to reduce the water resistance during submarine traveling It is 800 kilogrammes in weight and while out of use rests in a hold below the upper deck This hold is locked by a cover and when closed is only recognized from the slight projection of the stationary pivoting support which does not oppose to the water any resistance worth speaking of

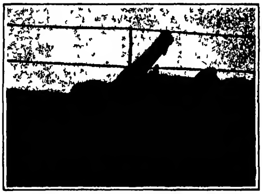
In erecting the gun and turning it down the socket rotates round a bearing situated close to the front edge of the stationary socket. In order to erect the gun the cover is opened and a bolt is loosened, after which the gun under the action of spiral springs, goes automatically into firing position It is maintained in this position by resilient bolts. Twenty seconds are required to get the gun into fighting order and to attach the breech sight and shoulder rest and the same time is occupied in removing these parts and stowing the gun away below deck

The tube of this gun is fitted with a ram lock and is made of non rusting nickel steel so that it may be stowed away in a compartment which is not water tight The cradle surrounds the cylindrical part of the tube and rests with its two horizontal trunnions in the bearings of the support On the cradle is arranged the braking cylinder with the spring for restoring the tube into firing position As seen from our pictures, the tube before being turned down is pointed vertically upward, being maintained in this position by a spring For this reason and in order to make the gun suitable for balloon and aeroplane defence, the upper part of the cradle support has been given a form allowing of considerable elevations. It may be said in this connection, that aeroplanes have already proved the most dangerous foes of submarine boats, it having been possible to sight from an aeroplane submarine boats traveling at considerable depths.

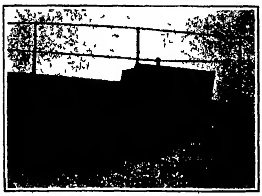
The pivoting socket has been given the shape of a column and carries at the top the bearing of the pivot It is widened out in its lower part, so as to form a case for receiving the hinge and resilient bolts. The shoulder serves to point the gun in the case of small elevations i e when used against the enemy's submarine boats, etc In firing at considerable elevations, e g., against aeroplanes the shoulder is turned round through an angle of 180 degrees The breech sight comprises a panorama angle telescope with universally rotating objective prism head. The eye-glass is not moved in taking aim

Firing is effected by means of a lever placed on the holder of the shoulder which is seized by the sighter with the left hand, while his right hand takes hold of the shoulder handle and his right shoulder is leaned against the cushion Three men are provided for operating this gun

Gun lowered, hatch closed



Bringing gun into firing position.



Gun lowered, hold about to be closed by shutters.

News From Mawson's Antarctic Expedition

THE Australasian Antarctic Expedition, under Dr Douglas Mawson, sailed from Hobart, Tasmania, in the ship "Aurora," December 2nd, 1911, for the purpose of exploring the great stretch of the Antarctic coast south of Australia, now usually known as Wilkes Land, extending from Victoria Land (the theater of Scott's and Shackleton's explorations) on the east, to Kaiser Wilhelm II Land (discovered by the "Gauss" expedition, in 1902) on the west This coast includes several minor "lands," sighted and named by various earlier expeditions, such as Adelie Land, named by Dumont d'Urville in honor of his wife, and the ever-problematical Termination Land, reported by the American expedition under Wilkes. The existence of Termination has been a subject of tedious discussion for a great many years. The matter may be disposed of by saying that there is no such land in the place assigned to it by Wilkes, but assuming the possibility that that officer made a rather gross error in his observations of latitude and longitude, excusable on the ground of weather conditions, he may have actually sighted the coast on which Wild's detachment of the Mawson party recently landed.

Mawson's expedition disclaimed any intention of pole-hunting. The party consisted mainly of graduates of the Australasian universities, and was generously financed and equipped. Dr Mawson himself is a well known geologist and magnetician, and had previous antarctic experience with Shackleton, when he was one of the three explorers who planted the Union Jack on the south magnetic pole. A radio-telegraphic station was established at Macquarie Island, and another in Adelie Land, where Mawson and a part of the expedition effected a landing in January, 1912. By means of these two stations it was hoped that messages could be relayed regularly between the Antarctic base of the expedition and the outside world, but only very recently have any wireless messages been received. After landing Mawson the ship cruised westward along the coast, and landed a second party, under Wild, at a point 1,200 miles from Mawson's station in February, 1912. The "Aurora" then returned to Hobart (about a year ago), bringing back the first detailed news of the progress of the expedition

The ship proceeded again to Antarctica last autumn for the purpose of bringing back the two land parties. Wireless messages have now come through—apparently from Adelie Land—stating that Mawson and six of his companions were unable to join the ship, evidently owing to unfavorable ice conditions, and will be forced to spend another winter (i. e., the summer of our hemisphere) in the Antarctic. A message from Mawson himself says

"Our sledging season has been very successful. We have opened up a large area of new land both east and west of Commonwealth Bay" (where his party landed) We have obtained important new data from numbers of stations in close proximity to the magnetic pole." The message also requests the royal assent to naming this new land King George V Land.

The expedition has unfortunately sustained the loss of two valuable members, viz., Lieut. B. E. S. Ninnis of the Royal Fusiliers, who was killed by falling into a crevasse nearly a year ago, and Dr Xavier Mertz, a Swiss scientist and champion ski runner

The Current Supplement

MR. F L. O WADSWORTH presents in this week's issue of the SUPPLEMENT the first part of the Preliminary Report made by the chairman of the Professional Committee to the Inventors' Guild.—Prof Bjerknes's inaugural address at the University of Leipsig, dealing with "Meteorology as an Exact Science," is reproduced in abstract.—Dr David H Ray discusses "The Skyscraper of the Future."—Mr James H. Wise describes an extensive hydro-electric power project in California.—A crude-oil Diesel engine of the horizontal type is illustrated and described.—Our readers with aeronautic interests will find an article on the Benoist flying boat, and a list of specifications of the requirements made by the U S. Government for scout type military aeroplanes.—Of the highest interest is the report of a remarkable meeting of the London Chemical Society, at which papers were read by Sir William Ramsay, Prof. Collie, and Mr Patterson, on an apparent case of the synthesis of matter This is further discussed in a special article by Sir J J Thomson, who, as our readers know, has for some time past been working with a highly ingenious and refined method of analyzing gases. On another page we reproduce his latest report on his work.—E. Marsden tells us how individual atoms are made visible and counted.

A Substitute for the Compass in Fog or Snow Storm

To the Editor of the SCIENTIFIC AMERICAN

As the result of a forced descent without compass from the observatory on Mount Rose (elevation 10,800 feet) in the heavy snowstorm of January 14th to 17th, the writer offers the following suggestion to persons who know the direction in which to start, but because of fog or blinding snowstorm cannot maintain the course with sufficient accuracy to reach their destination. However, two persons are essential to the carrying out of the plan, and snow is preferable to rocks or soil, because in the former any deviation is more noticeable.

Place the members of the party in a line forming the direction in which it is wished to go and sufficiently far apart, so that the man in the rear can observe enough of the trail made by the leader to determine whether it deviates from a straight line. If any deviation occurs, the suggestion "Right" or "Left" and "Steady" to the leader will be sufficient to bring him back to the course.

The Timing of Motor-boat Races

To the Editor of the SCIENTIFIC AMERICAN

I have been investigating the matter of timing motor-boat races, and have talked with several different persons who, in my opinion, know as much about the subject as anyone, but I have not been able to get many new ideas.

They generally agree on the plan of having some electrical communication between the mile posts at the start and the finish, and the preference seems to be for a telephone communication, because it permits of talking back and forth between the timers, enabling them to check their watches. They can also advise each other that such and such a boat is coming, get ready for timing, etc. I do not see much chance for improvement over this system, provided they have the installation.

If such telephone communications are not to be had, then it appears to me that signaling by flags is the most reliable, as any discrepancy in timing by this method need not vary more than one fifth of a second. This is not likely to be of such serious consequence, except where an error of one fifth of a second might throw an important prize to one competitive boat when it really belongs to another. Even with the telephone system there is always a chance of this much error, and favoritism on the part of the unscrupulous judges.

It is not an easy matter to time a boat accurately that is moving at a speed around fifty miles an hour, and the chances are that the boat would be a few feet either one side of the line or the other in taking the time. I like the idea of verifying the time by a photograph at the instant the time is taken, but this requires the perfection of apparatus which probably would not be considered, and for that reason it is likely to be a useless suggestion.

In England, at the Isle of Wight, the Admiralty have a half-knot course for testing their boats. One course is up the river, and the other is in front of Osborne, in open water. Where facilities are not good for the laying out of the mile or knot course, I think it would be much more practical to have the half-knot course. In Chicago, for example, such a course can be laid out on the Government breakwater, which runs in a straight line for more than a half mile, and the marks can be set up so that the boats can be run either outside or inside the breakwater, as desired. The advantage of the half-knot course is that flag signals would be very reliable.

In all cases fixed posts, and not floating buoys, should be used, and I believe that it would be a good idea if the man who calls time, or the man who sights the posts, had his vision of the approaching boat barred by a barrier of canvas or plank, so that he could not see the boat until it actually finished at the line.

A still more practical scheme would be a funnel-shaped apparatus of say ten feet in length, this apparatus being mounted rigidly on the line, so that the timer could look through it and sight the boat by two vertical lines or wires in the telescope-like funnel. All vision of the course and the strong outside light would be cut off from the timer's eyes by means of a curtain such as a photographer uses in adjusting his instrument. The object of this funnel-shaped apparatus would be to give the timer a limited field of vision, and the tendency would be to concentrate his mind and thoughts on the correct timing of the boat as it passed the line.

Racing boats can be steered as accurately as an automobile; and as races are usually held on water shallow enough to set up posts, boats might be made to pass close enough to a post to break an electrical connection (for example, a string stretched across the course a few feet above the water, so that it would be struck by a short mast, the string not being more than thirty feet long) otherwise it would be interfered with by the wind, and the length would be so great that the time would be less correct. In this case the breaking of the string would operate electrical timing apparatus, and there would be no chance for errors of judgment or questions of favoritism.

Aside from the methods and systems used in timing boats, the first important consideration is that the timing be done by some recognized authority, otherwise it will not have the value that it should have. Personally, I favor letting the American Power Boat Association have charge of all official timing of speed boats, and I believe that the sooner the motor-boat clubs of the United States and the people interested in the sport *recognize some representative association and* TAKE AN ACTIVE MANAGEMENT IN THE SAME, the sooner will we begin to make substantial progress, and motor-boat racing will not be the fiasco that it has been in the past.

The American Power Boat Association has recently adopted some restricted class racing rules which I think will prove very advantageous to the sport. These rules are along the lines that I have been advocating and writing about for the past two years, viz., the establishing of class based on maximum cylinder volume, as has been found practical in automobile racing, and also in boat racing abroad.

The feature that I wish particularly to emphasize is that no timing system is worth considering, or of much value, if the timing is not done by officials of some organized association.

To Upbuild the Merchant Marine

To the Editor of the SCIENTIFIC AMERICAN

In your editorial in the issue of January 9th you indorse the upbuilding of the American merchant marine in the deep-sea foreign trade by a return to the system that was in effect in the early days of the republic, i. e., the refunding of part of the duties to importers bringing their goods to the United States in American-built tonnage operated under the American flag.

This is only subsidy indirect, and like all indirect measures, the benefits would not equal the disturbance, neither does it appeal to the American mind of to-day to seek to do indirectly what is not allowed to be done openly.

One factor to be specially borne in mind in the application of differential duties in favor of American importers using American-built tonnage is that every commercial treaty now in effect between the United States and foreign countries would have to be abrogated ere differential duties could be put in effect.

That means a severe disturbance of business, and the way also is open to chicanery and fraud and litigation, and this without taking into account that no mention is made of any benefit accruing to shippers generally.

It is not to be disputed that large concerns importing goods in cargo lots would find benefit by the duty differential system, but to the rank and file of importers there would be no resultant good, in fact, it is a question if they would not find themselves at greater disadvantage as far as ocean rates go by the differential system than they are to-day.

In the many theories advanced for upbuilding the American merchant marine, particular stress is laid on the benefits that shipyards and shipowners and labor employed in shipbuilding will enjoy. But shippers do not appear to be taken into account. There has been no mention in these various schemes where the American shipper will benefit in the way of reduced rates and better service. The argument is steadily advanced by the advocates of subsidy and differential duties that by these means the difference in the cost of American shipping and American operation of tonnage will be overcome, but nothing is said of lower rates. If all the American public is to get out of the change is to pay the same rate of freight and pay an additional tax to the support of American tonnage in the foreign trade it is worse off in the last analysis than before.

We have one example of indirect aid to shipping now that would seem to be sufficient for the present—the free-toll bill to American tonnage engaged in domestic port trade between the Atlantic and Pacific. Free tolls to American coastwise tonnage is nothing but an indirect subsidy, and there is not the slightest testimony that free tolls will reduce freight rates one iota, nor is there evidence that it will stimulate the building of one additional vessel that would not otherwise be built.

On the contrary, this short-sighted measure has been denounced in every section of the country, not alone because it is contended that it violates the Hay-Pauncefote Treaty, but because it is an indirect contribution to an industry already protected as few American industries are, and from which no resultant benefits flow to the body of the American people.

One of the things that hold back the development of the American merchant marine is the crew regulations. A steamer of the United States has to carry several more men than does a foreign steamer, and it is not clearly shown what the benefit is. The American merchant marine is no freer from disaster than, we will say, the British merchant marine, and yet the crew requirements on an American steamer are much more onerous than on the British. Why the management of an American steamer is compelled by law to employ only Americans while the men that may be employed to build American steamers may be of any and every nationality is one of those things that is past finding out. Whatever the reason is the facts are there, and they add to the handicap that the American merchant marine suffers from.

And yet there is a ray of hope. The difference in the cost of building abroad in foreign shipyards is steadily lessening. To-day it costs to build in a British yard about \$40 per ton as against \$25 not so many years ago. The foreign shipyards are overcrowded with work; orders will not be taken for delivery till well into 1914. Here is an opportunity for the American builder. Why not try for orders from foreign shipowners? There is an urgent demand for tonnage. It is more than likely to continue for the next two years at least. The difference between the costs here and abroad for building the same type of steamer has narrowed down to about \$10 per ton. Perhaps some of our enterprising builders might cut the difference still further. Isn't it worth the trial? Especially as shipbuilding material is now on the free list, and the American shipyard is for the first time placed on a nearly even footing, as far as the first cost of its material is concerned. As a matter of fact to-day British shipyards are inquiring for material in the United States.

There is no question that an American merchant marine would be of benefit to every American industry, and if a plan is devised whereby the shipper, the laborer and the builder can all benefit, there will be but little hesitation in securing aid from the United States Congress. To bring this about, Congress could be induced probably, to consider paving subsidies to American-built ships operating to foreign countries, not adjacent, on a basis that would generously offset the difference in the cost between the foreign-built and American-built ship, and in addition half subsidies should be paid to American-owned foreign-built tonnage officered and manned by Americans and operated under the American flag.

All such steamships accepting subsidies should be forbidden to enter into agreements with foreign lines covering rates of freight or passenger rates, and the Interstate Commerce Commission or some such similar body should have the right to pass on the fares for passengers or rates on freight and to say that the same are fair and equitable. Acceptance of government aid should carry with it the right of government supervision.

Legislation for the aid of special industries is going out of fashion, if conditions are such that the assistance of the Government may justly be invoked, then the measure of the aid should be such that our manufacturers and exporters as well as importers and shipbuilders will also be benefited. This desired result cannot be brought about by any such indirect means as differential duties, whatever the benefits in the early days of the republic, they would under present conditions lead to a practical monopoly in many lines of ocean freighting.

Foreign governments would counter in a similar manner in favor of their own tonnage. American importers that are able to supply steamers with full cargoes would reap practically all the benefit, and to the average American importer or exporter no benefits may be looked for as far as lower ocean rates are concerned. The upbuilding of the American merchant marine should benefit our manufacturers, exporters, and importers equally with shipbuilders, shipworkers, and sailors. And if we are to have the foreign markets that our growing manufacturing industries demand, the American merchant marine must be in a position to make lower rates in case of need than can foreign steamship lines.

Conditions are more in favor of the American shipbuilder than has been the case for many decades. The cost of the material to the foreign builder is constantly increasing, due to higher wages, to higher cost of ore, and to higher cost of coal, whereas our output of iron and steel is increasing at a tremendous rate and it is fair to believe that the cost of material will be much in favor of the American shipbuilder in a comparatively short time.

Our trade between South American countries is rapidly increasing, and could be much more rapidly stimulated, were there American lines of steamers plying between South American and United States ports—fast steamers equal to, if not surpassing, the type of steamers that foreign steamship lines put on the service between South American ports and Europe. These steamers should be such as will attract passengers in goodly numbers, and we ought to aid them with adequate subsidy, but there should be no strings to government aid, it should be so broad that any American company wishing to engage in the ocean foreign carrying trade can secure a share of the aid on equal terms and conditions. This has not been the case with any measure of government aid introduced into Congress in recent years, and this phase of the past subsidy bills did more to kill off the various measures than opposition to the principle of subsidy itself.

Chicago, Ill. CHARLES DEFREEZE.

The Tallest Office Building in the World

Erection of the Woolworth Building, New York

FOR the present at least the tallest office building in the world will be found on the western side of City Hall Park where the towering Woolworth Building lifts its glittering steel and terra cotta structure through a sheer height of 785 feet above the sidewalk. This is not only the loftiest office building, but, if we except the Eiffel tower, it is the tallest structure of any kind as yet erected by man. Two other notable buildings in this city vie with the Woolworth tower in altitude, its nearest competitor being the Metropolitan tower at Madison Square with a total height of just over 700 feet, and the Singer tower, built like the Woolworth structure, on Broadway, and only a few city blocks to the south of it, which has a total height above the sidewalk of 612 feet. Mention should also be made of that remarkable structure on the opposite side of City Hall Park, the New Municipal Building, the top of the bronze figure with which it is now being crowned will be 560 feet above the sidewalk.

As the eye ranges up through the multitudinous stories of the Woolworth Building to the pyramidal structure at its top, the question arises as to what is the limit of height to which a habitable building can be carried. The answer is to be found in a certain restriction laid down by the Building Code of New York city, which states that on a rock foundation the load may reach but not exceed 15 tons to the square foot. It will surprise some of our readers to learn that on this basis, it would be possible on a plot of ground 200 feet square to erect an office building 2,000 feet in height, and to build it moreover, so that it would be perfectly secure against the fiercest hurricane, and, because of its elasticity, even against the altogether improbable event of an earthquake shock.

Some Dimensions and Quantities.

The Woolworth Building is taller than it looks. To reach its lowest foundation, we must go down in one place to a depth of 120 feet beneath the sidewalk—for that was the depth to which it was necessary to sink the pneumatic caisson in that particular spot before the solid rock of Manhattan Island was reached. This would make the total height of the building from lowest foundation to summit 905 feet. Just here while touching on the question of dimensions and quantities we may state that the building contains 23,000 tons of structural steel, 17,000,000 common brick, 7,500 tons of terra cotta, 1,800,000 square feet of floor tiles, 1,800,000 square feet of partition tiles, and 2,500 square feet of cut stone.

The construction of the foundation, etc., involved 100,000 yards excavation, the use of 24,000 yards of concrete, 400 tons of reinforcement steel and 150 tons of steel sheet piling. Finally, the building which with its furniture, etc., will weigh more than 125,000 tons will have cost, when complete, some $12,000,000.

The building covers a plot 155 feet by 200 feet. It is L shaped in plan, with two wings 00 by 05 feet, facing on Barclay Street and Park Place. The shorter side of the plot is that on Broadway. There are thirty stories in the main building, the roof of which stands four hundred feet above the street. From the center of the Broadway façade and flush with it rises a tower measuring 85 by 86 feet, which extends for an additional twenty-five stories above the roof. The building is carried on 66 concrete piers, sunk through gravel, sand and hardpan, everywhere to solid rock, which was found at an average depth of about 80 feet below the ground water level. These foundation piers are of solid concrete. The majority are circular and vary in diameter from 8 to 10 feet. A few of them are of rectangular cross-section.

Until the hardpan was reached, the sinking of the caissons was quickly and rapidly done, and one, 6½ feet in diameter, went down 80 feet in less than a single day.

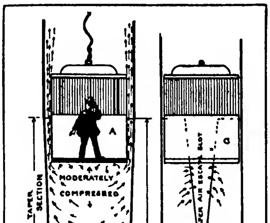
Erecting the Steel Frame.

Although the vertical axes of the majority of the columns coincide with the axes of the concrete piers below them, this is not always the case. Several of the columns are supported upon two piers, the piers being spanned by girders with the columns resting at about their center. Thus, in one column the load of nearly five thousand tons is carried at a center of a girder 8 feet deep, 6 feet 11 inches wide, and 23 feet long, which itself weighs over one hundred tons. Ordinarily between the piers and the foot of the columns is a grillage of several tiers of 24-inch I beams.

Naturally the columns in a building of this height ran up enormous dimensions and weights in the lower stories. Usually they were built in two-story lengths, and were of entirely inclosed box section, consisting usually of two channels with cover plates on both flanges. The largest column measures 34 inches by 30 inches, and its cross-sectional area is 660 square inches, that is to say, the metal in it, if compressed into a solid square bar, would measure 25 inches on each side. It is easy to understand from these dimensions that the total weight of the structural steel reaches 23,000 tons.

To Resist Wind Pressure.

When it is borne in mind that the storms which sweep across Manhattan Island, chiefly from the west and southwest, rise at times to cyclonic force and blow at a velocity of between 80 and 90 miles an hour, it can be understood readily that special provision had to be made, in designing so lofty a tower, to safeguard it against overturning or against failure in its steel frame due to the enormous bending stresses engendered. It is considered that for a building of this magnitude



The figure on the left illustrates the air cushion built with a tapering or flared top and as the elevator descends through this the air escape is automatically reduced. The vehicle being checked without violence in its fall. A and B show the car at different points in the inclosed shaft and dropping at different speeds. The other figure illustrates the same principle of the air cushion with a taper slot for the escape of the air taking the place of the entrance flare. The dropping car in combination with this slot automatically diminishes the passage for the escaping air.

Operation of the air cushion safety stop.

it is sufficient to estimate the average wind pressure, at maximum velocity, as 30 pounds upon every square foot of surface exposed. If we disregard the shelter afforded by the low buildings at its base, we find that the total wind pressure from top of tower to sidewalk over the whole surface facing a westerly wind is 1,800 tons, and this pressure may be considered as concentrated at a level of say about 300 feet above the sidewalk. It is evident, at once, that in order adequately to take care of this wind load, special features had to be introduced into the design of the steel framework. The inclined steel rafters of the spire-like roof of the tower take care of the horizontal thrust of the wind. Below the roof at the forty-second floor, the wind stresses are provided for by the wall girders and the columns, which are connected by deep gusset plates at their intersection. From the forty-second to the twenty-eighth floors, deep wall girders, made specially heavy for the purpose, are connected to the columns by double knee-braces. From the twenty-eighth floor to the street, heavy solid plates of steel, or "portals" as they are called, are constructed on the two sides and top of each opening or panel in the steel work. It was these portals that gave an appearance of enormous width to the columns before they were closed in by the terra cotta and stone work. On the Broadway front the portal girders are double as far up as the fourth floor, and they are no less than four feet in depth.

Fireproof Construction.

The floors of the basement and first story are built of reinforced concrete slabs, and the floors above of hollow terra cotta. The structural steel is protected against fire by a coating of concrete not less than one inch in thickness, or else by 3 inches of terra cotta. Wood as a material of construction is entirely excluded, the windows, the trim, the doors, are of pressed steel, and furthermore, the exterior windows where exposed are glazed with wire glass. In addition to the twenty-six elevators there are four wide stairways. A description of the installation of steam heat, ventilation apparatus, plumbing, drainage, gas and electric light, pneumatic service, etc., would make a long story by itself.

The building was commenced in September, 1910, and it is to-day practically ready for occupation. The rate at which the building was carried up is shown in the accompanying set of illustrations, which were taken from a lofty building on the opposite side of City Hall Park.

Safeguarding the Workmen and the Public.

An interesting feature of the construction of the Woolworth Building was the fact that the advanced ideas that underlie modern liability insurance were exemplified in an interesting manner, the inspection service rendered during the work being particularly worthy of note. The insurance company that carried the liability kept two inspectors on duty continuously, and immediately upon noting a condition which was likely to result in an accident, they notified the proper foreman or superintendent, and saw that the danger was removed. Their recommendations were also reported to the office of the engineering and inspection division of the insurance company, and written copies were then sent to the contractors.

Patent scaffolds were used for the bricklaying throughout the work, and these were covered, so far as possible, with substantial wire-mesh roofs, to protect the men at work upon the platforms from tools and materials that might fall from above. The sides of all the scaffold platforms were also protected by guard rails and by wire-mesh screens. Substantial bridges for the protection of pedestrians and others were built over the sidewalks, and these were made stout enough to resist the impact of any material that might fall upon them. Platforms 20 feet wide were also built out from the building at four different heights, to catch any material that might fall, and prevent it from descending into the street. Wire-mesh screens were arranged along their outer edges to give still further security.

All the hoisting apparatus was examined frequently and thoroughly by expert elevator inspectors, employees were not allowed to ride on material hoists, and the maximum number of persons who might be permitted to ride on a passenger hoist was definitely specified in each case. All hoists, whether used for the transportation of men or of materials, were covered overhead, to prevent accidents from falling objects. The hoist openings were effectively fenced, and were guarded by rails where the materials were loaded or unloaded. Openings in the floors were thoroughly guarded by rails or fences or otherwise. All stairways, whether temporary or permanent, were required to be rail guarded. Proper lighting was insisted upon, particularly at work places, along gangways and passages, and at every other important point. Warning signs were put up at all dangerous places. Laborers engaged in cutting concrete and other similar substances were obliged to use chisels fitted with protective handles, so that their own hands would not be injured if the strikers should miss the heads of the chisels. An effective watch was kept for nails and other similar sharp metal points projecting from the woodwork or from loose planks or boards or elsewhere. These are prolific sources of injury, and the men were required to remove them at once. First-aid cabinets were also provided, at the suggestion of the liability inspectors.

It will be apparent that the comparative freedom from accident that characterized the erection of the Woolworth Building was not the result of chance, but that it was the logical outcome of the practical system of inspection that was adopted.

A Remarkable Elevator Test.

The express elevators of the Woolworth Building

have a vertical travel of 676 feet, and Mr F T Ellithorpe, who is responsible for the safety system provided for the twenty-eight elevators, will make that sheer drop to demonstrate that his apparatus is equal to the maximum stress to which it may by possible mishap be subjected in service. What is technically known as an "air cushion" will first check the car and then bring it to a gentle halt From the bottom of each shaft upward for a distance of 137 feet the passageway is inclosed, forming the envelope of the so-called 'cushion." Of course, there are doors at each floor but these are closed mechanically as the elevators pass onward. The broad essential is that the surrounding casing shall be substantially air tight and that there shall be no escape for the air except upward past the sides of the descending vehicle. For the major part of its travel down this inclosed shaft, the space be-

Sir Joseph J Thomson.

What is Matter?

The Individual Molecule Revealed

To observe the infinitesimally small, we must impart to it proportionally intense properties Thus Sir J J Thomson shoots molecules with a muzzle velocity of 12,000 miles per second from an electric gun with a two-hundredth inch bore and from the pattern at the target deduces the mass of a molecule of which five thousand million million millions make a drop of water Molecules possessing a very high velocity are also known to us in a particles shot out by radium, which Sir William Ramsay has proved to be molecules of helium His latest contribution to science seems to point to the building up of the atom the synthesis of matter —EDITOR.

Sir William Ramsay.

Has Matter Been Synthesised?

An Account of Some New Experiments

By J W N Sullivan

THE immense amount of work which has been done on the radio active substances has rendered familiar to us the notion of the disintegration of matter We know that the last elements of the periodic table those possessing an atomic weight between 220 and 240, are not entirely stable but that the heavier elements are gradually changing into others of less atomic weight These elements disintegrate at very unequal rates, so that the element uranium takes 7 500 million years to change into the element radium while the average life of radium is only 2500 years. And the extraordinarily active substance known as radium emanation lasts on an average for only 5 4 days It is probable that the final stable form assumed by uranium in its successive disintegrations is lead, and that it passes through about thirty intermediate forms before it reaches this stage

It is an extraordinary fact that we find helium almost invariably associated with these changes. Helium whose atomic mass is 4, is a monatomic gas and is completely inert forming no chemical compounds Neither is it chemically absorbed by any substances whatever and of all gases it is the most difficult to liquefy Nevertheless, this uncondensable, unabsorbable gas was first found on earth (it had been known for some time to exist in the sun) in certain minerals which also contained uranium and thorium This fact in conjunction with those furnished by our study of the radio-active substances in detail leads us irresistibly to the conclusion that helium is one of the ultimate products of the spontaneous change of the elements. These phenomena of disintegration naturally cause us to ask Can the converse change occur in nature? Can matter be synthesised and the heavier elements built up by suitably operating upon those of less atomic weight? We seem now to be in a position to give an affirmative answer to these questions

On February 6th at a meeting of the Chemical Society in London Sir William Ramsay read a paper on "The Presence of Helium in the Gas from the Interior of an X ray Tube" and Prof Collie in conjunction with Mr Patterson read their paper on the presence of neon in hydrogen after the passage of the electric discharge through hydrogen at low pressures Sir William Ramsay on breaking old X ray tubes and analyzing the gases contained in the glass had found helium neon and argon the last named gases being two of the rare constituents of the atmosphere Last November, instead of breaking the bulbs, he had strongly heated them when again by spectroscopic analysis, he had found helium and neon So far the evidence is conclusive that helium certainly exists in old X ray tubes, but when we discuss its origin we are confronted by alternatives In working an X ray tube numbers of electrons are continually being shot out from the cathode It is indeed the sudden changes in velocity experienced by these minute bodies when they come in contact with the walls of the tube that give rise to X rays It is possible therefore that helium and neon existed in minute quantities in the cathode or the anti-cathode or in the glass of the tube, and that the violent bombardment of these by the electrons set the gases free. A further experiment of Sir William Ramsay's was to treat water with radium emanation. It was expected that helium would be found but actually neon was obtained. The atomic weight of neon is 20, and this suggests that it was formed by a combination of helium, whose atomic weight is 4, with oxygen whose atomic weight is 16. This suggested combination is borne out by the extremely interesting experiments of Prof Collie and Mr Patterson

Mr Patterson had thought that by doubling the charge on a hydrogen atom it might be possible to produce an a particle such as is shot out by radium and is known to be helium But on sparking the hydrogen Mr Patterson obtained neon

The possibility suggested itself that this neon came from the outside air the glass vessel conceivably allowing it to pass under the action of the electric bombardment. But on surrounding the tube by an outside vessel containing neon, and then helium, the same results were obtained as before. Further, the condition of affairs was not altered when the outer surrounding vessel was highly exhausted so as to form an almost perfect vacuum The neon still appeared in the inner tube in perceptible quantities. But the most startling discovery was made a few days before the meeting of the Chemical Society Prof Collie decided to test the outer highly exhausted chamber to see if there was anything in it On letting in a cubic centimeter of oxygen there was a slight explosion, due to hydrogen The oxygen was absorbed in the usual way by carbon but it seemed impossible to completely absorb it. On testing this residual gas by turning on the induction coil the tube was found to be ablaze with helium, with some neon mixed.

Mr Patterson made the experiment and found helium in the outer tube, but on varying the experiment by first filling the outer tube with oxygen, he found neon there So that we are again led to look upon neon as being formed by a union of helium and oxygen It would seem that the helium formed by the passage of the electric discharge in the inner tube has sufficient velocity to penetrate through the glass walls into the outer chamber and to combine there in some way with the oxygen to form neon.

If the helium in the inner tube is formed from the hydrogen, we may obtain some idea of the mechanism of this change by recalling some of the fundamental notions of the electron theory On that theory the atoms of all elements are made up of systems of electrons, the electrons being in a state of rotation according to certain laws. If now one of these complicated systems be struck by a free electron, moving with a velocity comparable to that of light, such as are produced in numbers in a cathode tube, we should expect something in the nature of a catastrophic splitting up of the original system, and the subsequent recombination might assume another of the standard forms which we call elements. Some time ago Sir J J Thomson published a very interesting investigation showing the way in which the various elements might be formed by appropriate groupings of their constituent electrons, and accounting for many of their chemical properties by this hypothesis.

Although the synthesis of matter is theoretically possible, yet before we admit that so important a result has actually been obtained, we must exercise a due amount of scientific caution. Thus the investigators whose work we have been describing point out that the gases found may have been originally present in the glass of the vessel or in the electrodes. However that may be, it is certain that in previous experiments of this kind, it has ultimately been found that such has been the case Sir J J Thomson, whose supreme eminence in this class of work cannot be questioned, is of the opinion that nothing further has been done in these new experiments than to liberate the gases already contained in the apparatus, and he points out the extreme difficulty of successfully eliminating these gases before subjecting the tube to the electric bombardment He had himself, as a result of his own experiments, believed for some time that he had discovered a new element of atomic weight three, obtained from the hydrogen in his tube but subsequent investigations had proved that this idea was unfounded [Sir J J Thomson's present view is that this substance is a polymerized form of hydrogen, as explained in another article on this page—EDITOR.] Sir Oliver Lodge and Mr Soddy are also inclined to think that the new experiments do not differ essentially from others in which observers had mistakenly supposed that they had accomplished the synthesis of matter So that we do well to be cautious. Science differs from other human activities in the superior quality of the evidence that it produces for its assertions, and it is a point of honor with a scientific man not to believe easily But whether future investigations confirm or refute the claim that matter has been synthesised, the new experiments have greatly aroused the interest of intelligent men and directed attention to matters which are usually ignored, and in that respect at least have done science a service.

In the World of Molecules

By Alfred J Lotka, M A., D.Sc.

MANY hundred years ago a Greek philosopher made an astute guess, that matter is composed of small particles, so small as to escape the direct observation of our senses, but themselves not further divisible—atoms. Centuries have lapsed, and it was reserved for this generation, not only to prove the existence of the atoms, but to weigh them and to count them one by one. (It must be remarked, however, that the typical atom is not incapable of further subdivision, according to the present state of knowledge.) What an exquisite achievement of scientific genius this represents, the reader may realize when he calls to mind the order of magnitude of some of the dimensions involved. It is almost useless to quote figures, as the mind fails to comprehend the immense ratios involved A graphic example is more helpful If a drop of water were magnified to the size of the earth, the molecules in it would be of the size of foot balls.

How, then, has the physicist succeeded in measuring, weighing and counting these elusive particles, utterly beyond the reach of the ordinary microscope, whose power is exhausted in detecting structures some thousand times greater in linear dimensions than a simple molecule? Even the ultra-microscope extends the limit of visibility only a little farther, to particles about fifty times smaller than those discerned by the microscope.

An exhaustive answer to the question raised cannot be given here. For details the reader must be referred to the splendid articles by Svedberg, Aston, and others, which have appeared in recent issues of the SCIENTIFIC AMERICAN SUPPLEMENT. We must content ourselves here to pick out one or two points of special

interest How has the physicist accomplished the stupendous feat of counting individual molecules?

Radium, which, fifteen years ago, came upon the scene of physical science, holds the key to this, as to so many wonders of modern science

If the atom of helium is small, it possesses a terrific velocity when shot out (as an α particle) from a radium molecule undergoing disintegration. Such an atom, moving at the rate of 12,000 miles per second, a speed which would carry it from the earth to the sun in the space of two hours, is allowed to impinge upon a screen of zinc blende, where it produces a visible flash of light, a scintillation as it is termed technically This fact has been made use of in counting helium molecules.

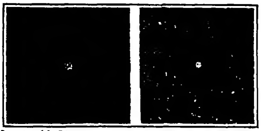
But the art of the physicist does not stop here. He is not dependent on the bounty of nature for his supply of rapidly moving molecules Sir J J Thomson in his monumental researches, has taught us how to train a miniature gun at a target and shoot molecules with one tenth the speed of light Charged molecules moving at such speeds behave like electric currents, and, like these are deflected by a magnetic field. The amount of this deflection, and of the deviation produced by an electric field, enables the observer to determine the mass of the molecule. The molecule, as it were, is made to weigh itself, and to register its weight on a photographic plate.

No wonder with such methods as these that Sir J J Thomson is reaping a harvest of remarkable new discoveries. The delicacy of the process is such that by its means quantities of helium for example, which the spectroscope fails even to reveal, are not only detected and identified but are made to register their atomic weight (The quantity of substance required is about one hundredth of a milligramme or one three-millionth of an ounce) Only the chemist, who knows the intricacies and tedious labor involved in an atomic weight determination by ordinary methods, can fully appreciate the significance of this. The chemist too, may presently learn to appreciate the value of a method which enables us to deal with molecules or radicles having a brief life of one ten millionth part of a second. It may perhaps appear at first sight as if a substance of such short duration could not possibly ever gain any practical interest But it must be remembered that in every chemical reaction matter must pass through transient stages intermediate between two compounds. While the existence of such evanescent states of matter has been more or less vaguely realized and has been clearly referred to by Schönbein for example the chemist using the ordinary established methods of work was utterly incapable of even approaching the study of these transient states of matter Sir J J Thomson has now shown us the open door through which this domain of chemistry may be approached, and we may expect that the future, perhaps not the immediate future, will bring important elucidations in this direction, and will perhaps, among other things, give us an insight into the *modus operandi* of catalysers. As it is, Sir J J Thomson has observed such transient substances as CH, CH_2, CH_3, and others. Another discovery which is not yet fully explained is that of a substance having molecular weight 3. It is difficult to explain this in any other way than by attributing it to triatomic hydrogen H_3, although no such substance had hitherto come under observation.[1] The gas has been obtained by submitting various materials to cathode ray bombardment, and Sir J J Thomson inclines to the view that it is originally contained in these materials (aluminium, platinum, etc.) and is in some way released by the bombardment. These observations have quite recently acquired particular interest through the publication of a paper by Sir William Ramsay, Prof Collie and Mr Patterson, who have obtained evidence of the apparent formation of helium and neon under remarkable circumstances. It may be that these gases are present initially and are merely released under the conditions of the experiment.

[1] Sir J J Thomson's latest report on this subject, a lecture before the Royal Institution, is reproduced in this week's SCIENTIFIC AMERICAN SUPPLEMENT, to which the reader is referred for details. He will there find also some very significant comments by Sir J J Thomson on the work of Ramsay, Collie, and Patterson, while another article in the same issue describes the experimental arrangement employed for observing the "scintillations" referred to above.

Optical Illusions; Trust Not Your Eye

THERE is an old proverb "Seeing is Believing" Like many old sayings, it is far from being fully justified We believe and justly in the existence of many things that we do not see such as for example molecules, and what is at times even more important, we cannot always trust uncritically to the seemingly plain evidence of our senses. How very much we are subject to error of perception and of memory has been well brought out by Prof Münsterberg among others, in his well known popular exposition "On the Witness Stand" But even a mere sense-perception, quite apart from pranks played on us by our deficient and deceitful memory may be deceiving to an almost unbelievable extent Various "optical illusions," as they are called, have long been known and we reproduce herewith several classical examples, together with two or three of more recent origin which surpass all others in their convincing" power



By courtesy of La Nature

Fig 1.—A pattern made up of oblongs? No, concentric circles!

Fig 2.—A spiral which is not a spiral. What is it?

Three of the illustrations shown here belong to one type- in each case the optical illusion relates to certain angles. Thus, in Fig 1 the horizontal lines appear bent converging at their ends. As a matter of fact, they are perfectly straight and parallel A similar effect is produced in Fig 6 by the cross hatching, which gives a zigzag appearance to a set of parallel straight lines. In Fig 7 you are asked to trace one line *ab*, which is partly covered up Is *ab* straight, or is *ac* straight? Answer the question by eye, then try a ruler to prove your answer

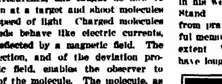


Fig 3.—What is the form of the central white band in this drawing? Try it out with a ruler

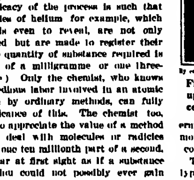

Fig 4.—What is the relative length of the horizontal lines in the four figures above?

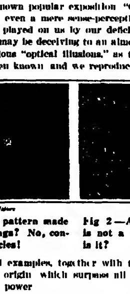

By courtesy of La Nature

Fig. 5.—In selecting material for a garment it is well to consider the deceitfulness of appearances.

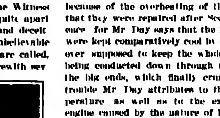

Fig 6.—The long lines appear to run in zigzag You may not believe they are parallel until you have measured the space between them

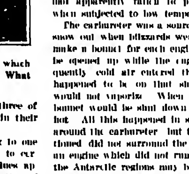

Fig 7.—A "straight" line which is not a straight line, and one which is.

A somewhat different type of illusion is illustrated in Fig. 4 In this case it is the length of a line which is deceptive. Of the horizontal lines in the four parts of this figure, which is the shortest, and which the longest? Measure them with a ruler and see

But of all optical illusions the most convincing are those shown in Figs. 1, 2, and 5. Do you see the spiral on the right, Fig. 2? Well, it is not a spiral but a set of concentric circles! You do not believe it? Get out your compasses and try As for the figure on the left, how would you describe its pattern? See what the compasses say about it

Our last illustration may appear somewhat frivolous. We might draw from it the practical lessons that it pays to consider the effect of the pattern of your trousers if you are vain about the shape of your legs.

Scott's Motor Sledges

IN a recent number of *The Car* Bernard C Day discusses the sledges that Scott took with him on his ill fated antarctic expedition Day's account is interesting because he drove one of the sledges Moreover he had previously been in charge of a motor van with Capt Shackleton's expedition of 1907 to 1909

Scott took with him two motor sledges each capable of carrying two tons. Mr Day states that the sledges covered one hundred miles over soft surfaces upon which rested from two to eight inches of snow The top of this surface seemed to have the consistency of sand rather than of snow at very low temperatures. The sledges were driven by 14 horse-power air cooled engines with the cylinders cast in pairs. Mr Day states that the engines worked splendidly although Scott himself stated in a paper sent to civilization just before he made his dash for the pole that they were stalled because of the overheating of the engines. It may be that they were repaired after Scott narrated his experience for Mr Day says that the front pairs of cylinders were kept comparatively cool by a fan, which was, however supposed to keep the whole engine cool the heat being conducted down through the connecting rods to the big ends, which finally crumbled to pieces. This trouble Mr Day attributes to the great range of temperature as well as to the excessive strain on the engine caused by the nature of the surface over which the sledges had to travel The heat however did not melt out the white metal On examination the phosphor bronze was found to have become crystallized and had apparently fallen to pieces, as aluminium does when subjected to low temperatures and undue strain

The carbureter was a source of anxiety To keep the snow out when blizzards were raging Mr Day had to make a bonnet for each engine and this bonnet had to be opened up while the engine was running Consequently cold air entered the carbureter if the wind happened to be on that side and then the gasoline would not vaporize When the engine missed fire the bonnet would be shut down and the engine would run hot All this happened in spite of the exhaust jacket around the carbureter but the jacket it must be mentioned did not surround the choke tube The fact that an engine which did not run hot in Norway ran hot in the Antarctic regions may be attributed to the intense dryness of the southern atmosphere

In a dispatch published in the New York *Times* Commander Evans states that Scott and his companions after having determined that they were within half a mile of the pole marched on to the desired spot taking with them their motor sledge and there planted the Union Jack Can it be that Scott had underrated the motor sledge in his earlier accounts?

Buying Oil in Original Packages

HOWEVER thoroughly he may have studied the mechanical construction of his car the average automobile user pays but scant attention to the matter of lubricants. He buys some widely advertised brand of oil and trusts to the honesty of the garage keeper that the oil asked for is supplied. While the better class of dealers give the particular brand demanded, the temptation to substitute is unquestionably yielded to by the less scrupulous. Just as some wine dealers supply five different varieties of wine from a single cask, so the dishonest automobile supply dealer or garage keeper sells many different brands of lubricants from a single barrel Since many oils are alike in color it is difficult to identify the lubricant thus supplied The motorist's best safeguard is to follow the practice of wise housekeepers of buying only in original packages. Practically every known trade-marked brand of oil is sold in barrels, half barrels, and in five-gallon tins. The name is on the containers, and in most cases the containers are sealed Unless the motorist buys in these original packages he has usually but little assurance that he is getting the oil he asks for Therefore, the trade-marked and labeled tin is to be preferred in most cases.

A New Tire for Motor Trucks

By C. Francis Jenkins

IN motor truck construction, the tire problem has yet to be solved. Motor, transmission and steering gear have been worked out to a practical basis but tires do not wear correspondingly. The life of the solid rubber motor truck tire is so short that tires cost more than all the other running expenses added. The tires do not wear out, they simply go to pieces under the pounding of the cobble-stone streets. And the thicker the rubber the greater the loss. For this reason thin tires are frequently recommended for heavy trucks, rubber being employed almost exclusively.

If therefore something can be found which will give as good traction as rubber, cost less and wear longer, it will merit serious consideration and extended tests. Wood seems to fulfill these conditions admirably and so tests of wooden tires were undertaken.

Wood is proving its good qualities in similar service, i. e., in street paving, ferryboat and warehouse flooring, and such other surfaces as are subjected to excessive attack. It has been so in use for a long time, and has proved superior to other materials, especially in its excellent adhesive qualities. Its surface does not become slippery in wet weather.

These qualities, i. e. good traction and long wear, recommend the use of wood as a truck tire and at first the question seemed simply a matter of selection of the suitable wood. After a long search and much experimentation a wood was found which seemed to lend itself admirably to this service. And it could be had in sufficient quantity, *and*, fortunately, is not very suitable for anything else. It is close-grained yet soft enough to make it practically noiseless, and so tough that it cannot be split with an ax. The grit of the roadway buries itself in the tough end grain of the wood and provides most excellent traction as good as solid rubber in dry weather and a thousand times better on a wet street.

There was one initially insurmountable difficulty however, the tire would expand when it got wet and then when it dried out again the blocks would separate and the tire would go to pieces. The contraction and expansion wasn't much, to be sure, but it was enough to ruin the tire. This difficulty was finally overcome by the very simple expedient of imbedding in the tire a powerful spring band either a heavy spiral spring entirely inclosed in the tire, or sinuous flat spring bands located in a shallow groove in the tread of the tire. The blocks which constitute the tire are doweled together laterally inclosing the spring band, and then after being thoroughly dried the tires are placed in a vacuum chamber and impregnated with a water repellant.

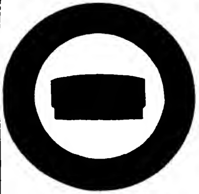
Such a construction makes the tire integral and capable of being handled, shipped, marketed and used as conveniently as a rubber tire. They should, of course, be made in all standard sizes and in such widths of tread as may be required by the loads to be carried.

Thus apparently an entirely satisfactory tire for motor trucks has at last been evolved. A tire made up of blocks of wood set like street paving blocks, with the grain end on to the point of attack, that is with the grain of the wood radial to the wheel, and having a powerful spring band imbedded in the tire to hold the blocks in place and compensate for longitudinal contraction and expansion. It is easily and quickly secured in place on the wheel, the driver simply unbolts the old rims, throws away the worn out tire, and replaces it with the new tire.

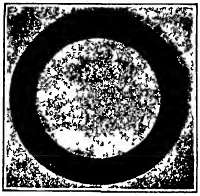
These tires will travel over softer ground, last many, many times longer than solid rubber tires, and cost but a small fraction as much as rubber for the same loads. They are noiseless, and give better traction and do not skid on wet pavement.

Wooden tire showing peripheral spring band.

At first it was thought that perhaps, the use of solid wood tires might transmit too much shock to the motor mechanism but this was disproved in actual service, as shown by the records made in an instrument for showing the vibration and shock when the wheel was shod with solid rubber and then with the new solid wood tires.



Wooden tire, made of blocks and fitted with demountable flanges. In center is a cross-section of tire, showing imbedded springs.



Wooden tire before flanges are applied. It is set with the grain end-on, that is, the grain of the wood is radial to the wheel.

An electric meat slicer fitted with an automatic knife sharpener

The Tismer engine, showing the method of feeding fuels of different types.

An Automatic Sharpener on an Electric Meat Slicer

By Frank C. Perkins

THE accompanying illustration shows a novel automatic meat slicer which is operated by either an electric motor or by hand, and is an efficient labor saving device.

The first useful slicer was invented in 1890 by Mr. W. A. Van Berkel, a practical butcher of Rotterdam, Holland, and this machine was a great advance on the old method of slicing by hand knife. After a time, as with most inventions, experience proved that the machine was not a perfect proposition as one of the most important defects was the impossibility of keeping the knife sharp enough to prevent loss of waste meat due to damaged slices.

The secret of the successful working of this new slicer with an automatic sharpener is in maintaining a keen edge on the knife all the time. The automatic sharpener is an ingenious device, is always ready for use and is operated by simply turning the handle of the machine. The work is done in a few minutes, it keeps the knife in perfect condition, and is readily adjusted to take up wear. It saves time and labor and abolishes the risk involved in the use of the old hand stone.

A knife guard is provided which prevents the operator's hand coming in contact with a knife, and it is so arranged that the user cannot cut himself, hence is far safer to handle than the ordinary hand knife.

Should the electric motor be out of commission the slicer can be converted to hand power in a few seconds. The electric motor is belted to the slicer from below the counter, the slicer being fitted with intermediate gear for use in speed reduction.

An Engine That Will Run on Several Fuels

THE present high price of gasoline and the probability of still higher prices in the future have brought the fuel question into such prominence that more than ordinary interest attaches to any plan that promises relief or suggests possibilities in the way of lowering construction and operation costs.

Whether or not the motor designed—or to speak correctly converted—by P. G. Tismer of New York is all that is claimed for it in the way of a consumer of heavy oils of almost any kind, remains to be proven by actual commercial service in the hands of disinterested users. In the mean time one motor now is running to demonstrate the principles involved. It is in the hands of the inventor, however, who cannot, even if he would, handle the engine as a stranger would handle it. That there is much that is of interest in the engine, however, may be gathered from the fact that it runs on various hydro-carbons ranging in density from gasoline and crude oil to gas house tar without other adjustment than the changing of the feed valve opening, that there is no special fuel feeding mechanism, such as a pump, pressure system or spraying device, that there is no cooling system, either air or water, and that though there are no rings on the piston there is apparently no more loss of compression than in an engine with a ring-packed piston.

The Tismer engine is an old-fashioned machine of the vintage of the days of hot tube ignition, with certain alterations in more or less important details. It operates on the straight four-stroke Otto prin-

ciple, however, and cannot in any way be compared with engines operating on the Diesel principle.

It has a single horizontal cylinder with a bore of 3⅛ inches and a stroke of 4⅝ inches, both valves are in the cylinder head, the inlet valve being of the automatic type. The changes that have been made tend to simplify rather than to complicate. The cylinder has a water-jacket, which, however, is empty, the water pipes having been removed and the jacket left merely a useless appendage. A new piston has been made, the chief characteristics of which are that it is a plain cylinder with no packing grooves, fitting the cylinder with a clearance of one half thousandth inch all around, and that it is deeply recessed at the head. The recess forms by far the greater part of the combustion chamber, and the piston approaches very near to the cylinder head.

The intake pipe with its throttle valve remains, but there is no carbureter, the pipe is a plain air intake and is fitted with a valve. The oil feeding mechanism consists of a small pipe leading from the fuel tank directly to the cylinder head into which it opens through a brass fitting. Oil is drawn in by suction, and is not sprayed or otherwise atomized. The spark plug is unusually located in the brass fitting that serves to connect the oil pipe to the cylinder head and its two electrodes are separately mounted and insulated, for convenience in altering the spark gap. High tension ignition is employed.

At each intake stroke of the piston, the oil drawn in passes over the spark plug points and has a cooling effect that is increased by a small current of air admitted to the fuel pipe back of the intake check valve. It seems probable that this column of air has some slight effect in breaking up the oil in addition to cooling the spark points. However, the engine runs as well without it as with it except that without it the plug points burn away rather quickly, which form of plug trouble caused much annoyance until the opening was made.

In order to make it a simple matter to run the engine alternately on any one of several fuels, the intake pipe is connected through a header having several branches leading to six small open fuel tanks containing kerosene, fuel oil, machine oil, gas house tar and the condensed oil that collects in the muffler, and is drained out from time to time and again fed to the motor. Each of the pipes is fitted with a stop cock.

As far as can be judged from watching the operation of the motor, it will burn any of the fuels in the tank with equal facility and will run at practically the same speed no matter which one is fed. The same holds true of any combination, though it would seem that when two or more cocks are open at the same time the lighter liquid forms the principal ingredient in the fuel. Unfortunately, the motor runs without load and, therefore, there is no way of determining its power on the various fuels. It is said that for a considerable period the motor was run regularly, driving the machine tools in a small shop, and that the results obtained were relatively the same as when running light. During half an hour's running there was no indication of overheating, despite the absence of the cooling system. There was no difficulty in throttling down to a very low speed and acceleration was fairly good if not remarkable. Instead of regulating the amount of fuel admitted in altering the speed of the motor, or of throttling the air passage, speed is reduced merely by admitting exhaust gas to the air intake pipe. This has the effect of reducing the amount of oil burned, the unburned portion being thrown out with the exhaust, where it drains into a sump and is re-fed to the engine.

When the motor is perfectly cold it will start readily on crude oil after two or three revolutions, it will not start on kerosene or any of the other fuels until heated, when, however, it will start readily on any of them except the oil drained back from the muffler. As to the formation of deposits, it would seem that they are avoided either by adjusting the fuel feed so accurately that there is no residue or by feeding considerable excess fuel part of which is burned and part thrown out with the exhaust. The latter method is preferred as the simplest, as very little care then is required in adjustment. The running of the motor with an excess of fuel is attended by considerable volumes of smoke with many particles of burning fuel in the form of sparks and a small amount of red flame though the temperature of the exhaust is comparatively low. With the fuel feed correctly proportioned the exhaust is exceedingly clear and is free from objectionable odors.

The ringless piston is the result of the inventor's opinion that piston rings serve no more useful purpose than to scrape the cylinder walls so clean of oil that it must be constantly replenished, moreover, that the thin film instantly is effected by the heat. Consequently the engine has been constructed upon the theory that the piston should "float" on a comparatively thick film of oil as a journal in its bearing, that the layer of oil if thick will not be effected by the heat in the short space of time required for the explosion, and that considerably less heat will be dissipated through the cylinder walls. In fact the compression of the motor is very good not only when the cylinder is cold and the oil thick, but when it is hot and the oil presumably is considerably thinned. The compression is very close to 100 pounds to the square inch.

Unfortunately no accurate tests of any kind have been made with the Tismer engine, fuel consumption, horse-power efficiency still are unknown quantities. Apparently, the inventor has concerned himself only with the production of a motor that will run on any one of a variety of fuels without material adjustment, special effort having been made to utilize gas house tar which may be purchased in some localities for as little as a cent a gallon. Laboratory tests soon are to be made, however, when we hope to be able to give a more accurate account of its efficiency, both thermal and mechanical.

The Equity Rules and Patent Causes

THAT the new equity rules will unquestionably reduce the cost and time involved in patent litigation, is almost a certainty. One of the rules states that "in the trial of a patent cause whether in open court or by deposition or partly in each way, only one expert witness shall be allowed to each side unless leave shall previously be obtained from the court on motion made and cause shown."

Whenever in the opinion of the court intricate technical or scientific questions of fact are involved in the cause the court will upon consent of all parties, appoint some disinterested person skilled in the art to act as an assessor. This assessor is to sit with the judge at the hearing of the evidence, and is to help the court in its deliberations. In this manner, the court will be able to appraise conflicting testimony properly.

The voluminous testimony which has been an unfortunate feature of patent litigation of the past is to be cut down. When testimony is taken by affidavit the witnesses shall not give their opinion as to the meaning of any patent claim or specification, but their testimony shall be strictly confined to an explanation of the operation of relevant arts, processes, machines, manufactures, or compositions of matter, and of the meaning of terms of arts or science, and of diagrams or formulæ."

Death of Tolbert Lanston

TOLBERT LANSTON, patentee of a number of inventions, but whose most important invention was that of the Lanston type-setting machine, generally known as the monotype machine, died at his home in Washington city on February 18th.

Mr Lanston early evidenced his inventive genius and took out numerous patents for inventions having more or less utility, but did not achieve any considerable or marked success with his inventions until he approached the problem of the type-setting machine which resulted in the issue of patents to him for the well known Lanston machine. This machine has gone into extensive practical use and forms the basis of a large commercial or manufacturing establishment.

Mr Lanston was born in 1844 in Ohio, and after a brief service in the Ohio volunteers in the civil war was appointed a clerk in the Pension Office at Washington, in which office he gradually arose to the position of chief clerk. He graduated at law and was admitted to the bar but on the completion of his important invention resigned his office and devoted his attention thereafter for some time to the invention. Some years ago he suffered a stroke of paralysis, which left him an invalid.

Trade-mark Notes

Trade-mark of a Selling Agent.—In Strawn v Ontario-Cucamonga Fruit Exchange, first Assistant Commissioner Billings in holding that a fruit exchange which is the selling agent for several associations of fruit growers is not entitled to register a mark used by all of them, said: "Each of the associations, therefore, having the right to use the mark during its membership in the exchange and the latter being merely a selling agent for these associations, it cannot be held that the latter has such ownership in the mark as will entitle it to registration."

Similarity of Trade-marks.—First Assistant Commissioner Billings in the trade-mark opposition of Holt & Co v Kansas Milling and Export Company, has decided that in determining the similarity of trade-marks three features must be considered—first the appearance of the words, second the sound of the words when spoken and third, the significance or meaning of those words and applying the reasoning, holds that the word "Nobility" was properly refused registration in view of the prior use by another of the word "Noblesse" as applied to the same goods.

Life-boat Apparatus.—Patents Nos. 1,043,914 and 1,043,915 have been granted to John E Erickson of Chicago. In the former a life boat is disclosed, whose structure is closed on all sides with an upwardly projecting tower and a hatchway in the upper end of the tower and a step-ladder arranged in the tower, the lower end of the tower being closed by a door and the upper end by a hatchway and a stair being provided which leads downwardly from the door into the hold of the structure. In patent No 1,043,915 are provided two spaced supporting rails with boats arranged between the rails, with studs at their ends, which rest upon the rails together with means which engage the studs, so that the boat may be moved longitudinally along the rails and lowered at the ends.

A Novel Convenience for the Filing of Patent and Trade-mark Applications.—In a decree of August 27th 1909, the Peruvian Government authorized certain of its consulates abroad to receive applications for the registration of trade-marks and by decree dated July 22nd, 1910, a similar provision was made for the filing of applications for patents. The Peruvian Government has attributed the lack of complete success of these measures for facilitating the registration by foreign applicants, to the fact that foreign patent attorneys have not come to realize that they can deal directly with the Peruvian Consulates. Certain charges are fixed and the provision seems a wise and a fortunate one especially in connection with cases in which the early filing of an application is desirable or necessary and a similar provision on the part of many of the other foreign countries would doubtless be viewed with favor.

Notes for Inventors

Branding the Dough Before Baking.—In patent No 1,044,170 William C Horner, of Indianapolis Ind describes a method of producing bread in which the dough is branded by locally applied heat after which the branded dough is baked.

A Novel Arrangement of Locomotive Cabin.—Thomas F F Lee, of New York city, has patented No 1,044,190 a locomotive in which the cab is at the front end the water tank at the opposite end and a boiler and fuel receptacle are located between the cab and the tank.

A Woman's Device for Prolonging Sleep.—In patent No 1,047,163 Helena M S Bullock shows a device for prolonging sleep in which an eye shield or band of light absorbing material extends from temple to temple over the eyes, has at each end a loop to fit around the ear to hold the eye shield in place.

A Novel Swab.—Hobart DeLancey Rapson of Philadelphia, Pa has secured a patent, No 1,047,704 for a toilet swab which consists of a large number of paper strings detachably bound together for a portion of their length by a binder which is so united as to be removed by water to release the strips.

Sentiment and a Dog Cracker. You would not expect sentiment in a dog biscuit but it is there. A patent has issued on the invention of Carleton Ellis of Larchmont New York, for a biscuit in which the dog-food mixture is molded in the shape of a bone with knob-like ends to render it attractive to dogs and to make it capable of being readily grasped by a dog.

Convertible Motor Boat and Automobile. Hartley A Mitchell of Newport News, Va has secured patent No 1,047,271 for an automobile boat which combines an automobile body and has a boat hull together with detachable wheels and detaching means which are operable from within the boat and hoisting means which are operable after the detachment of the wheels for raising the wheels into the boat.

Convertible Boat and Sled.—William Offenburger of Evergreen N Y has secured patent No 1,048,337 for a boat which has a detachable sleigh attachment comprising runners and a cradle supporting the boat with steering mechanism operable from the boat and connected with the runners and propelling means in the form of a bladed propeller operating in the air so it can drive the device either in or out of the water.

The Lazy Man's Fire Lighter. Earl Norris Swan and Alton Beightol of Scotia Cal in a patent No 1,048,172 show a fire lighter in which a match holder located in the fire box of the stove has a heating wire which holds the head of a match and an electric circuit includes the match-holding member and a circuit closer located alongside of the bed so the match can be lighted electrically without getting out of the bed.

Harnessing Child to a Bed or Couch.—Ida M Brown of Somerville Mass provides means for securing a small child to a bed or couch. This as shown in her patent No 1,048,031 includes a cross-shape anchor composed of two straps provided near their ends with safety pins by which they may be secured to the bed or couch and at the crossing point there is secured a belt on which are suspender-like devices for going around the child's shoulders, the entire device being easily applied for use.

An H Ward Leonard Patent. H Ward Leonard of Bronxville N Y has patented an electrically propelled vehicle, No 1,042,008 in which he develops upon the vehicle itself by means of a gasoline engine the power employed in the propulsion of the vehicle which power is transformed into electric energy through dynamos, and this energy is supplied to propelling motors at such a voltage and current as will cause the vehicle to travel at the speed desired. The invention also affords a simple arrangement for holding the vehicle stationary when either going up a grade or going down a grade and without brakes.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel

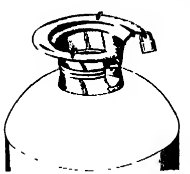
SHIRT WAIST SUPPORTER.—F. WINSLEY, care of Bartholo Manufacturing Company, Glendale, L. I., N. Y. For the purpose of this invention use is made of a tubular covering, a band extending through the covering and terminating in loops projecting beyond the ends of the covering, and a tying string doubled up to form an eye for engagement with one of the said loops.

REMOVABLE HEEL.—L. KATINS, care of Midget Manufacturing Company, 178 Center St., New York, N. Y. This invention has reference to boots and shoes, and its object is to provide a new and improved removable heel arranged to permit the user of the boot or shoe to conveniently and quickly replace the worn out heel by a new one.

Of Interest to Farmers.

CANE STRIPPER.—G. R. LUCE, corner Ingan Ave. and St. Peter St., New Orleans, La. This invention concerns itself with sugar cane harvesters, and the object is to produce a machine which can be advanced along the rows of cane, and which will operate to top the stalks of cane and strip the leaves from the stalk.

MILK CAN COVER.—H. G. THOMPSON, Campbell Hall, N. Y. The object here is to provide a cover which will form a perfectly tight closure for a vessel and be capable of being securely locked in closing position so as to prevent access to the can by unauthorized persons. For this purpose the inventor con-

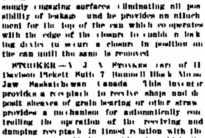


MILK CAN COVER.

structs the neck of the can and the closure which is fitted to the same so as to have snugly engaging surfaces, eliminating all possibility of leakage, and he provides an attachment for the top of the can which co-operates with the edge of the closure to enable a locking device to secure a closure in position on the can until the same is removed.

STOOKER.—A. J. A. STOCKER, care of H. Davison Pickett, Suite 7, Hammell Block, Moose Jaw, Saskatchewan, Canada. This inventor provides a receptacle to receive shape and deposit sheaves of grain bearing or other straw, provides a mechanism for automatically controlling the operation of the receiving and dumping receptacle in timed relation with the operation of a binder machine to which the stooker is connected and whereby the same is operated, and provides means for adjusting the operating mechanism of the stooker to vary the timed relation to the operation of the binder.

EYEGLASS MOUNTING.—L. E. CURTIS, I. O. O. F. Block, Main St., Windsor Locks, Conn. The invention provides a mounting having pivoted nose clips pressed on by springs and arranged to prevent the pivot from becoming loose accidentally, and to allow of taking off the springs and replacing the same without disturbing the rest of the mounting. For this purpose use is made of a bridge connected with lens clips and provided with pivots for nose clips to swing on, the springs coiled on the pivots and bearing at one end on the nose clips and engaging at the other end flattened portions on the pivot.

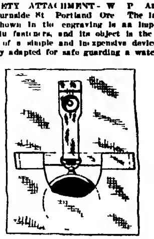


EYEGLASS MOUNTING.

INCUBATOR.—C. H. IRA, 1115 Hurney St., Omaha, Neb. This improvement provides for controlling distribution of heat within the radiating chamber, provides a mechanism for controlling the passage of heat into the chamber, and provides means disposed on the outer side of the incubator whereby the disposition of dampers for controlling the heat passages may be ascertained.

Of General Interest.

SAFETY ATTACHMENT.—W. P. ALDEN, 227 Burnside St., Portland, Ore. The invention shown in the engraving is an improvement in fasteners, and its object is the provision of a simple and inexpensive device especially adapted for safe guarding a watch by

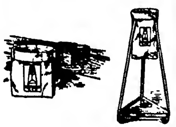


SAFETY ATTACHMENT.

attaching it to the clothing wherein a support is provided for the watch which will permit the watch to be taken from the pocket for inspection and returned without releasing the watch from the fastener or the fastener from the clothing.

BOTTLE LABEL.—G. ZITZMANN, care of Frank Shoreys, 40 Steuben St., Middle Village, L. I., N. Y. This invention relates to labels for bottles and other containers used for drugs and the like, and has reference more particularly to a label comprising a transparent face plate and a background sheet having a name or the like printed or otherwise produced thereon affixed to the back of the face plate, the label having a glazed or enamel appearance.

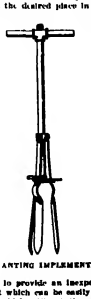
SANITARY REFUSE BAG.—J. F. RANKER and ELLEN D. RANKER, 852 Park Ave., Brooklyn, N. Y. This invention provides a sanitary refuse bag and holder for the same more especially designed for receiving refuse in households, hospitals and other establishments, and arranged to provide a convenient and cheap means for receiving and bagging the



SANITARY REFUSE BAG.

refuse for ready transportation to a place of disposal. For this purpose use is made of a bag provided at its mouth with an outwardly extending annular fold, adapted to engage a supporting ring for suspending the bag and for holding the mouth thereof open for the reception of the refuse, the fold being capable of being extended or drawn out to form a closing means for the bag after the same is filled.

PLANTING IMPLEMENT.—N. P. JENSEN, Ephraim, Utah. The invention has reference more particularly to implements which comprise means for receiving the plant and then setting it into the desired place in the ground.



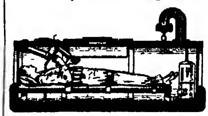
PLANTING IMPLEMENT.

The object is to provide an inexpensive planting implement which can be easily and quickly manipulated, which will set the plant in any desired position in the ground without injury to the plant. This implement is also intended for pressing the soil uniformly about the plant set in the ground.

FOLDING CROSS.—A. H. SMITH, care of Hans T. Walrow, Astoria, L. I. City, N. Y. The principal object here is to provide a cross as an article of jewelry adapted to be worn as a watch charm, the structure being provided with a pivoted member whereby it may be hung from a chain, this member being adapted to engage one of the pieces of the cross in order to bring it out of register with the other piece.

FENCE CLAMP.—J. C. MCHENRY, 1906 Grand Ave., St. Louis, Mo. This invention is an improvement in wire fence clamps and has for its object the provision of a novel construction whereby fencing material such as ordinarily found on the market, or similar material, may be clamped for stretching or for other purposes.

LIFE-SAVING VESSEL.—JUDSON DAVIS, East Rochester, N. Y. The object of this invention is to provide a life-saving vessel for

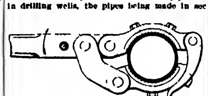


LIFE SAVING VESSEL.

use in connection with steamships or the like by means of which a person can be saved in case of shipwreck or on similar occasions, in which the person to be saved can remain safe and comfortable despite severest storms, in which the person can be freely supplied with pure air, which can be emptied of vitiated air in which water inadvertently entering can be ejected when necessary, which will not readily be injured by rocks or floating obstacles, in which the passenger is carried safely with respect to sharks and the like, and in which means are provided to prevent clogging of the air inlet valve by the freezing of water about the same. The right to manufacture this device is for sale.

Hardware and Tools.

WELL DRILL WRENCH.—W. R. OSBORNE, R. F. D. No. 7, Box 32, Palestine, Tex. In this case the invention is an improvement in large pipe wrenches, which are particularly designed and adapted for use on drill pipe used in drilling wells, the pipes being made in sec-



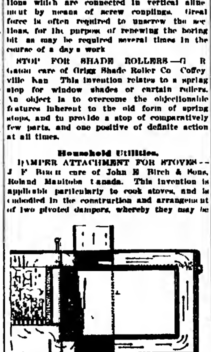
WELL DRILL WRENCH.

tions which are connected in vertical alinement by means of screw couplings. Great force is often required to unscrew the sections, for the purpose of renewing the boring bit, as may be required several times in the course of a day's work.

STOP FOR SHADE ROLLERS.—G. R. GATON, care of Grigg Shade Roller Co., Coffeyville, Kan. This invention relates to a spring stop for window shades or curtain rollers. An object is to overcome the objectionable features inherent to the old form of spring stops, and to provide a stop of comparatively few parts, and one positive of definite action at all times.

Household Utilities.

DAMPER ATTACHMENT FOR STOVES.—J. F. BIRCH, care of John E. Birch & Sons, Roland, Manitoba, Canada. This invention is applicable particularly to cook stoves, and is embodied in the construction and arrangement of two pivoted dampers, whereby they may be



DAMPER ATTACHMENT FOR STOVES.

operated simultaneously for closing one and opening the other to control the circulation of the products of combustion, whereby they may pass directly to the escape flue or be diverted to pass around the oven.

COOKING STOVE.—J. R. LEONARD, 53 Kimball Bldg., Cedar Rapids, Iowa. The oven is arranged above the firebox and is so constructed that the former is ventilated and the heat evenly distributed throughout. A direct draft is heated to an intense heat before entering the fire from below the firebox, and a secondary draft is heated to an intense heat before being admitted above the bed of the burning fuel.

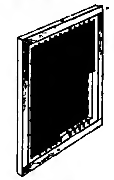
FLY TRAP.—G. CHRISTON, Box 273, Pearl River, N. Y. Among the principal objects which this invention has in view are to provide a device which is economical of construction and simple of operation, and to provide a device having a fixed annular receptacle and

FLY TRAP.

a removable central receptacle of liquid, together with means for readily removing the central receptacle. The operation is based to a large extent upon the known peculiarity that insects rarely will crawl downward over a relatively vertical surface.

CLOTHES PIN HOLDER.—H. B. STEBBINS, R. F. D. No. 2, Oelwein, Iowa. This holder is for use in connection with laundry work, and it comprises a frame having means for holding a plurality of clothes pins ready and available for immediate use and means for supporting the frame from the person of the user.

WINDOW SCREEN.—V. CARANNA, 145 Bleecker St., New York, N. Y. Among the principal objects which the present invention has in view are: to provide means for permitting and for inducing the escape of flies from the rooms provided with the screens, to



WINDOW SCREEN.

provide means for reversing the operative position of the screen, and to provide traps for the capture of flies when passing through the screen. The engraving shows a perspective view of the screen, part of the netting having been removed to show the construction of parts otherwise concealed.

Machines and Mechanical Devices.

DRIVING BELT.—H. U. SMITH, Station B, Route No. 1, Columbus, Ohio. In this instance the invention refers to belt gearing and has particular relation to a driving belt for use in high speed transmission devices and particularly in connection with belt gearing in which there is employed a power pulley of a relatively small diameter.

DUMPING AND CLEANING APPARATUS FOR DIGGING MACHINES.—H. W. SARGENT, Fort Dodge, Iowa. This invention relates to digging machines of the type wherein buckets or scoops are made to fill themselves by being scraped along the surface of the ground to be excavated as the end and sides of a trench or ditch.

VALVE.—J. J. MAYER, 366 Lenox Ave., New York, N. Y. This valve is for use in flushing tanks and similar devices, and is arranged to insure a powerful closing with a view to prevent leakage, to present a different surface of the valve disk to its seat at each operation, to insure its long life and to prolong the period of its repairing or rewashering.

PNEUMATIC PLASTERING MACHINE.—P. L. CROW, 110 Livingston St., Elizabeth, N. J. This invention insures the delivery of a plastic mass, such as plaster, to a distant point, to permit of cleaning the pipe connections, and allows the operator to automatically shut off the supply of the plastic mass, and to signal to the machine operator in case the mass from one supplying chamber is exhausted so that another supplying chamber can be connected up to supply more plastic material and to avoid delay in supplying the mass where needed.

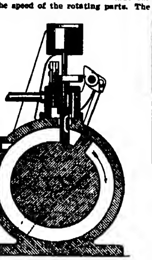
PLATFORM SCALE.—W. H. DRAUGHON, 10 Lack Bldg., Nashville, Tenn. The invention provides means for causing all parts of the platform to move vertically at the same velocity at any point of the [illegible] by that

weighing lever, and reduces wear and friction in the moving parts of said means. The means heretofore employed for the first purpose may be adjusted so as to accomplish the desired result while the weighing lever is occupying a substantially horizontal position, but as the lever passes from this position the imperfection of the means heretofore used is such that, under certain conditions, a perfectly parallel movement of the platform is not maintained.

GEARING.—O D. ALSPACH, Lancaster Ohio. This invention relates to gearing, and has for its object one having wheels with gearing for pulling taut a rope or chain secured to a fence, there being a bearing movable relatively to the wheel in which a gear wheel is journaled for meshing with the first mentioned gearing, so that the first mentioned wheels may be rotated by the said gear wheel when the bearing is in normal position, and the first mentioned wheels may be rotated freely independently of the gear wheel when the bearing is moved away from the first mentioned wheel

Prime Movers and Their Accessories.

ROTARY ENGINE.—J MCRAE, Caryville Fla This invention relates to a rotary engine and particularly to the means for controlling the steam inlet valve and to the means for governing the speed of the rotating parts. The

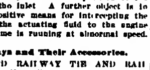


ROTARY ENGINE.

object is to provide an engine having a steam inlet actuated by the relative position of the piston and the inlet A further object is to provide a positive means for intercepting the passage of the actuating fluid to the engine when the same is running at abnormal speed.

Railways and Their Accessories.

COMBINED RAILWAY TIE AND RAIL FASTENER.—H A Basquier St. Croix Falls Wis. In the present patent the invention has reference to a combination steel and wood tie and an improved form of rail clamps, the

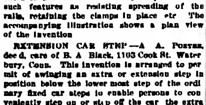


COMBINED RAILWAY TIE AND RAIL FASTENER.

wood members of the tie seating on the hollow steel tie body, and in turn forming seats for the rails. It is the design of the inventor to improve in various particulars the devices indicated to the end that efficiency be promoted in such features as resisting spreading of the rails, retaining the clamps in place etc The accompanying illustration shows a plan view of the invention

EXTENSION CAR STEP—A. A. FOSTER, dec'd, care of B. A Black, 1103 Cook St. Waterbury, Conn. This invention is arranged to permit of swinging an extra or extension step in position below the lower most step of the ordinary fixed car steps to enable persons to conveniently step on or step off the car the extra or extension step when not in use being folded out of the way so as to form no obstruction while the car is in motion

SMOKE PREVENTING DEVICE AND ECONOMIZER FOR LOCOMOTIVES.—E KOHAN, 2046 Madison Ave., New York, N. Y An object here is to provide a novel means for causing a secondary combustion to consume

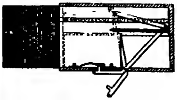


SMOKE PREVENTER AND ECONOMIZER FOR LOCOMOTIVES.

and utilize the heat from the unconsumed particles that pass from the locomotive firebox to the smoke-stack. The inventor takes up the heat from the gases and products when at their highest point of heat, and utilizes the heat thus conserved to aid in producing a secondary combustion in a smoke-pipe The heat developed he utilizes for heating a fluid, preferably atmospheric air and the heated fluid is in turn utilized for any available purpose in connection with a locomotive or train. In a preferred arrangement, he employs the heated air for promoting combustion in the firebox

Pertaining to Vehicles.

SIGN AND INDICATOR—V FICCIO, Tampa, Fla The invention pertains to signs or indicators, especially those adapted to be carried at the rear of automobiles to indicate the direction in which the vehicle is about



INDICATOR FOR DIRECTION OF VEHICLE.

to turn The main object of the improvement is to provide a sign of light weight which may be operated mechanically to project into view a slide bearing a legend or word showing the direction in which the vehicle is about to proceed.

RESILIENT TIRE—R L. JENKINS, 2204 E West Cary St Richmond, Va. An object of this invention is to provide a resilient tire which shall take the place of the pneumatic tire in ordinary use but which can be manufactured for much less cost and which is not subject to the danger of deflation due to punctures or blow-outs

VEHICLE AXLE—J E. HADGAN Winter pock Va This improvement is in axles having detachable journals or spindles and particularly in that class in which the axle ends are slotted and the journals or spindles provided with shanks adapted to fit in such slots. The invention provides a more easily effected and a more secure automatic engagement, and avoids weakening the axle by the construction required to effect such engagement

SPRING TIRE FOR VEHICLE WHEELS—H J CASEY Keeseville N Y An object here is to provide metallic springs for tires to be used as a substitute for pneumatic tubes to which the various members constitute a unit the elements of which are so formed and arranged as to permit of the unit being quickly placed within the ordinary shoe

SPEED GEARING G Q SEAMAN 101 Ralph St Brooklyn N Y The invention provides a speed gearing for automobiles and other vehicles and devices, and is arranged to permit the operator to readily change the speed from a low to a medium or a high speed or to reverse without moving any of the power-transmitting gear wheels out of mesh

Designs.

DESIGN FOR A KITE—H E WILSON care of Johnson & Larimer Dry Goods Co Wichita Kan In this ornamental design the kite simulates the outlines of a garment, with front and side pockets buttons fly trousers legs, etc the whole keeping within the lines of the ordinary kite

DESIGN FOR A PLATE DISH OR SIMILAR ARTICLE—F BOOTE and J B BOOTE 46 W Broadway New York N Y This ornamental design is of a plate or dish of circular form the border comprising a double band of twist design another band of the same encircling near the center a large cluster of flowers Between the outer and central bands flowers are grouped with charming effect

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each Please state the name of the patentee title of the invention, and date of this paper

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents subscriptions books etc This will greatly facilitate answering your questions as in many cases they have to be referred to experts The full name and address should be given on every sheet No attention will be paid to unsigned queries Full hints to correspondents are printed from time to time and will be mailed on request.

(12756) G E S asks I have heard of a method of finding a spring of water Take a limb of a plum tree which has a crotch in it Take the two prongs of the crotch in the hands and hold the limb horizontally Walk along and when you walk over a spring of water the stick will be attracted to the ground Please let me know through your valuable paper what condition of the wood (dry or green) gives best results What size of limb should be used? Can any other kind of wood be used? To what depth can a spring be detected? Is this method successful when the ground is covered with snow? What causes the branch to dip? One person told me that when he heard of it he didn't believe it but the first time he tried it the branch was attracted so that it broke A We must say that we do not know anything about the finding of water by means of a crotched stick nor do we believe it can be done As a boy we lived in the country where wells were depended upon for water and we saw not a few men use the witch hazel stick It was said then that the stick must be of witch hazel You say it should be plum One is doubtless as good as the other We have seen many failures with the sticks and have known men to dig deep where the stick had turned down vigorously without any water being found Sometimes water was found but if there is a divining rod of any value water should always be found when it indicates water with any force We cannot be of any help to you in explaining the divining rod The rods used were usually green freshly cut

(12757) N G asks Would you be kind enough to inform me how to use the figures written as follows 1.3×10^{-6} and others like them with a positive exponent? These numbers are in constant use in works on radio-activity and the higher branches of science A A negative exponent indicates division In the example which you propose it requires that the decimal point be removed six places to the left thus 1.3×10^{-6} = 0.000 001 3 This is as you see thirteen ten millionths If the exponent were positive it would indicate multiplication by 10 thus 1.3×10^{6} = 1 300 000 The decimal point is to be removed six places to the right This is a device to save time in writing and space in printing

(12758) H R R asks 1 What causes the moon to swing back and forth from north to south? Sometimes rising far to the north and again far to the south and are these vibrations regular? A The moon moves in an orbit around the earth which is nearly in the same plane as that of the earth around the sun its orbit being inclined but 5 degrees to the plane of the ecliptic This will cause the moon to change its points of rising and setting along the horizon each month as the sun does through the year only a little more Since the full moon is always opposite the sun in the sky it follows that it will rise farthest to the north of east in the winter when the sun rises farthest to the south of east and *vice versa* in the summer This motion is perfectly regular and is repeated every month but it does not occur at the full of the moon every month and is not usually observed excepting at or near the full of the moon 2 What is the construction of the electric switch used on automobile starters? When it is closed the motor starts the engine and when it is released the motor turning in the same direction becomes a dynamo and charges the accumulator I was always under the impression that a motor turned in one direction and a dynamo in the other A You are correct in your general statement that a motor will run in an opposite direction to that of a dynamo which generates a current of the same polarity For the construction of the particular switch we must refer you to the makers of the switch The makers of the automobile will probably also be able to give you the information you ask 3 What causes the sun to appear to grow larger when it approaches the horizon and become oblong in shape especially when setting behind a thin bank of cloud? A The sun and moon appear larger at their rising and setting because of our comparing them with the objects on the horizon They are immensely more distant and larger and so give us the impression of growing larger How this happens you can see by making this experiment Take three inches on a sheet of white paper Divide it carefully in half Mark off one half into eighths of an inch, by making dots with a pencil and leave the other half in one clear space The space filled with dots will appear the longer although you have made it just equal to the open space. It is an optical illusion of which we cannot rid ourselves 4 Do the fixed stars change their time of rising through a course of years, or do they always rise at the same time? A The stars rise and set every day about four minutes earlier by the clock than they did the day before, and thus they seem to move around the sky every year Notice any bright star for a month, and find that it is farther west by about 30 degrees at the end of the month than it was at the beginning at the same hour of the evening.

NEW BOOKS, ETC.

AN INDUCTIVE CHEMISTRY By Robert H Bradbury, A M, Ph D New York D Appleton & Co, 1912 8vo, 437 pp, illustrated

Prof Bradbury's endeavor has been to produce a textbook that shall stand the test of the student viewpoint Every portion of the book has been tried out again and again in actual class work By regarding each separate subject as a problem by bringing first the everyday knowledge of it into play and by augmenting this knowledge by experiment the interest of the study is kept up and the growing intelligence and knowledge keeps pace with the introduction of new problems. The method and arrangement of the work is good, and satisfactory results will doubtless follow its adoption in class study

SLEEP AND THE SLEEPLESS Simple Rules for Overcoming Insomnia. By Joseph Collins M D New York Sturgis & Walton, 1912 12mo, 120 pp Price $1 net

However much one may believe in the efficacy of counting sheep in occasional cases of sleeplessness it is certain that only a long-continued *regime* of simple worry free living can really cure the old insomniac. Dr Collins who is physician to the Neurological Institute of New York makes no claim to short cuts in the cure of sleeplessness but does embody in his work in easily understandable terms the latest results of scientific study The cause of the malady is first sought the requisite quantity of sleep for the individual is determined and the curative agencies are described Opiates and narcotics hypnotism and suggestion are all duly considered and their advantages and disadvantages weighed in the balance Mental attitude position breathing food and drink exercise—all these influence sleep in a marked degree and no one of them has been neglected in the chapter on treatment

HOW TO READ A DRAWING By Vincent C Getty Philadelphia J B Lippincott Company, 1912 8vo, 64 pp, 62 illustrations Price, $1 net

In a very attractive series of papers Mr Getty comes near to proving his original proposition—that the reading of a drawing is really a very simple accomplishment and that to be able to read and understand common English is all the education necessary to its acquirement He makes a strong plea for the usefulness of the accomplishment justly urging that in the industrial world no work of importance is undertaken without the aid of drawings He has employed as few technical terms as possible has given a sufficient number of actual examples to impart to the text a highly practical value and has in fact succeeded in his purpose to help the man of little education to a thorough knowledge of the reading of mechanical and architectural drawings.

CELLULOID Its Manufacture, Applications, and Substitutes By Masselon Roberts, and Cillard Translated from the French by Herbert H Hodgson, M A, B Sc, Ph D Philadelphia J B Lippincott Company 1912 8vo 356 pp, illustrated Price $7 50

In the absence of any adequate literature on the subject of celluloid and the processes of its manufacture this capable translation from so authoritative a source will doubtless receive a hearty welcome The authors have aimed at a complete and practical work in which processes and their relative values are conscientiously studied and discussed Methods of working materials time required for the various operations consumption of raw materials cost of labor and power and cost of installation all receive attention in the various divisions of the volume Among the objects of manufacture specifically dealt with are combs umbrella handles hollow articles celluloid linen phonographic cylinders, buttons and teeth

INTRODUCTION A L'ETUDE DE LA METALLURGIE Le Chauffage Industriel Par M Henry le Chatelier Angers A Durdin et Co, 1912

This volume as its preface informs us is a reproduction in book form of the lecture course in general metallurgy at the Ecole des Mines The volume comprises two distinct parts. The first devoted to heating discusses successively general phenomena of combustion natural and artificial fuels and furnaces The second part devoted to the study of metals and their alloys, discusses successively the constitution and the properties of iron-alloys and of metals other than iron The high position occupied by the distinguished author of this book is in itself a sufficient guarantee of its excellence The greatest scientists have been the greatest teachers If any evidence were needed to that effect this book would adduce it. On every page one perceives how one of the greatest of living metallurgists has drawn from his ripe experience and presented it in a form which will enable the student to profit by it Although in a scientific text-book which is intended primarily for the use of students, one does not expect to find anything but clearness of exposition Prof Le Chatelier has gone out of his way to present his subject as gracefully as the limited possibilities before him would permit. The result is a book which may be regarded not only as pre-eminently fitted for the use of the student in metallurgy but one which that same student will read with some degree of pleasure.

TRANSACTIONS OF THE AMERICAN CERAMIC SOCIETY Volume XIV Columbus O, Published by the Society, Secretary's Office, 1912.

Salt-rising Bread

(Concluded from page 229.)

ural question. Without a doubt, it is largely a matter of taste The bread is different. With the first bite, one will notice its distinctive odor and flavor, which to many people is decidedly agreeable Its relative digestibility and wholesomeness remains undetermined. It may be truly said, however that it is eaten by many with perfect safety, while yeast bread causes indigestion

This research promises to prove of practical value. Plans are already made by which a leaven, containing the newly-discovered bacillus will be put upon the market for home and bakery use The introduction of this product should eliminate failure and improve the quality of salt rising bread generally

In the meantime if any of my readers' desire to make salt rising bread, they will find the following tried recipe a good one

Recipe for Salt-rising Bread.

Yeast—Take one cupful of sweet milk in a quart cup Place cup upon stove until milk boils well Stir into the boiling hot milk five or six teaspoonfuls of white corn meal to which a pinch of soda has been added. Wrap up well, and set in a warm place overnight, or until it is light

Sponge—Pour one and one fourth cupfuls of water as hot as the hand can bear in a bowl and add about two cupfuls of flour Then add the yeast from the quart cup and stir with a spoon until mixed. Place the bowl in a warm place until the sponge rises well about one to one and one half hours. A good way to keep the sponge warm is to place the bowl in warm water The water should be at body temperature or warmer

Dough—Take one and one fourth cupfuls of hot water (almost boiling) and dissolve in it four teaspoonfuls of sugar one teaspoonful of salt, two teaspoonfuls of lard and add six or seven cupfuls of flour Then add the sponge and mix well Add more flour if necessary to make a rather soft dough Mold the bread into loaves at once Put in a warm place to rise one to one and one half hours and bake in the usual way

Salt rising bread is close grained, and it should not be made as light as other bread

Some readers may be curious to know why this bread is called "salt rising" bread Of course, salt has no leavening power There is no light on this question in literature. The name was probably chosen because the leavening power was not understood, and it was thought that salt in some mysterious way caused the rising

Left Side Steer and Center Control in Motor Cars

(Concluded from page 2?1)

when sitting on the left is no more difficult than judging distance on the left when sitting on the right. In the situations where the most accurate steering usually is needed the chauffeur can see the adjoining wheels of both vehicles concerned, and also the road between them. When the car that is being overtaken is steered from the left the chauffeur is in the best possible position for he can see exactly what the other car is doing and can act accordingly

Undoubtedly there are many peculiar situations where right side steering would have, the advantage over left-side steering, but there are just as many emergencies in which the opposite would be true, so that matters may be said to be balanced so far as extraordinary predicaments are concerned It is in the ordinary, every day phases of motor car driving that left-side steering appears to the best advantage, emergencies must be dealt with as they occur

With the increasing appreciation of the good points of left-side steer has come a realization of the great convenience of centrally located control levers—that is, the gear-shift lever and the emergency brake lever—and the combination of left-side steer and center control is one that

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY You will find inquiries for certain classes of articles numbered in consecutive order If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information There is no charge for this service *In every case it is necessary to give the number of the inquiry* Where manufacturers do not respond promptly the inquiry *may* be repeated

Munn & Co., Inc

Inquiry No. 9285 Wanted factory store shop or bank articles to sell by canvassing at a profit of from $1 00 to $5 00.

Inquiry No 9286 Wanted household novelties or business necessities which can be retailed at from $1 to $2.

Inquiry No. 9287 Wanted to buy a machine which will reduce cobs to meal—not a machine for shredding the cobs, but a machine that will pulverize them.

Inquiry No. 9288 Wanted the names and addresses of concerns that can coat steel balls with pure tin one-sixteenth of an inch thick.

Inquiry No. 9289 Wanted substance melting at 225° and hardening when cold without imparting any flavor to tobacco smoke and without exhaling any oil or fatty vapor

Inquiry No. 9290 Wanted name and address of a manufacturer of a patented device which is suitable for making up pay envelopes, namely, to fold up bills and insert them with minor coins in a pay envelope of the usual size.

Inquiry No. 9291 Want to buy machinery for manufacturing wooden toothpicks.

Inquiry No. 9292 Wanted a gum that will stick labels to grape-fruit.

Inquiry No. 9293 Wanted the names and addresses of manufacturers of waterproof cloth also samples of such cloth

Inquiry No. 9294. Wanted to buy glass balls 1½ x 1¾" in diameter

Inquiry No. 9295. Wanted name and address of some glass manufacturing company who can make patent lamps.

Inquiry No. 9297. Wanted names and addresses of manufacturers of dogs saving household conveniences goods.

is embodied in a number of very well known cars and promises to achieve much greater prominence As center levers usually are arranged, the driver has little or no difficulty in passing them, and so can dismount from the car on either side. If a passenger is beside him he will politely climb out into the road If not, he will alight on the sidewalk The passenger in the front seat is not annoyed by being forced to move every time the chauffeur wants to get out, or by having the chauffeur squeezing past From the chauffeur's point of view there is no particular in convenience in changing from right to left steer with center control, because the right hand, accustomed to handling the levers, still does the work Even when the levers are placed on the left side however, it is not a particularly difficult matter to become accustomed to the new position

With regard to what may be called naturalness of position it is said that a driver who has been accustomed to right side steer has very little difficulty in adjusting himself to the conditions that obtain in steering from the left On the contrary however, drivers who have become thoroughly familiar with the left side position find it decidedly difficult to get used to right side steer and, it is said, never quite overcome a feeling of awkwardness that is not usually felt after a little experience by those who change from right to left.

The Tallest Office Building in the World

(*Concluded from page 227*)

tween the elevator and the envelope is just enough to permit the increasingly compressed air to gradually slow up the car and finally to bring it to a standstill

The falling elevator is substantially a loosely fitting piston but even so, it would be stopped with a violent jar after entering the inclosed shaft if some provision were not made for regulating the initial compression of the confined air. A jar of this sort would be enough to throw the occupants to the floor of the elevator and might easily be the means of breaking their bones if not hurting them more gravely But the air pressure will be controlled by automatic valves. The designer has two other ways of regulating the air pressure which are illustrated herewith

Mr Ellithorpe has already dropped more than three hundred feet without injury and the car has been so gently restrained and halted that water was not spilled from a brimming tumbler In the test in the Woolworth Building Mr Ellithorpe will drop in the car a sheer distance of 530 feet, and in that interval the elevator will attain a maximum velocity of two miles a minute—that fall will be made in less than six seconds, and the remaining 117 feet of confined air will be counted upon to overcome that momentum and to stop the car progressively For the test, the ordinary cables will be detached, and a single rope with a tripper, subject to Mr Ellithorpe's control, will be substituted.

By means of a large number of gages, which will be fitted for the first time in tests of this sort, records will be taken of the air pressures at each stage of the drop within the limits of the air cushion and engineers are much interested in the data which will be obtained in this way

It is interesting to note that as the falling distance is four times the stopping interval, Mr Ellithorpe will, during the latter interval, have his weight increased fourfold. Some time ago, during a test of this sort, the occupant of the car was seated in a chair When his weight was increased by the retardation of the car, the chair was crushed, and the passenger was fatally injured by a splinter

Our thanks are due to Mr Cass Gilbert, the architect, W Gunvald Aus, the structural engineer, and the Thompson-Starrett Company, the contractors, for courtesies rendered during the preparation of this article.

Chemical Balance and the Fire Waste Problem

By Sidney G Koon

WHAT happens when you touch a match to the kindling in your kitchen stove? The simple and obvious answer seems to be— It burns That is true enough so far as it goes but the answer does not even suggest the complicated and far-reaching results that are accounted for by the very simple chemical principle involved in the lighting of a small fire

In a mass of paper and kindling wood we have various forms of carbon The flame of the match heats a portion of this carbon until the carbon combines rapidly with the oxygen of the air that is to say a small part of the kindling burns or oxidizes and from this small start the process of burning or oxidation spreads rapidly to every carbon compound that can be heated by the fire *up to the point* where it will *combine* with oxygen Of course all this is an old story but there may be new morals to old stories and there is a new moral to this story if we look at it from a certain point of view

From this point of view all burnable materials represent a state of unstable equilibrium A big wooden dwelling for instance may feel and look almost as solid and enduring as a mountain yet in point of fact it is made up barring the nails and other hardware of a great mass of carbon compounds that a little push in the shape of a few hundred degrees of heat will completely upset

The upsetting is not quite so instantaneous as the fall of a vase which you may knock off the table with your elbow but once give that heat push in the right place and the overturning of the carbon mass that we have been calling a house may be very rapid indeed Moved by this initial heat-push the carbon in the floors the wood finish the clapboards the roof the framing the outside paint and the inside furnishings all rush into combination with the oxygen of the air and what was a house carpets tables and chairs curtains becomes suddenly a rising whirlwind of carbon oxide and carbon dioxide it goes up in smoke and heat

This conception of every burnable substance as being in such a state of balance that a small push at some appropriate time will upset and destroy that substance is of more practical value than may appear at first sight It is perfectly true of course that many houses have for scores and some even for hundreds of years survived the upsetting chances of human carelessness while every day others get the little heat push at the proper moment and in consequence are overturned and destroyed

The more interesting field for the application of this idea is the vast number of large buildings for manufacturing or for office use whose size greatly increases the possible magnitude of a chemical overturning due to the heat push and whose occupation by a large number of human beings gives to such chemical upsetting something more than a merely scientific interest If we apply the idea carefully and logically we shall find that this notion of a chemical balance which may be suddenly and completely overturned by a relatively small application of a few hundred degrees of heat is a pretty comprehensive and at the same time a fairly exact guide in the matter of preventing the start of serious fires and of limiting the extent of the chemical overturn after it has once got under way

Naturally the first lesson is that this chemical overturn will not affect substances whose carbon is in such shape that it will not combine when heated with the oxygen of the air This suggests right away the use of stone, brick, terra cotta and cement for building materials, and so far as the oxidation overturn is concerned the materials named are satisfactory, or perhaps it would be better to say that they were combined in buildings only so far as they are capable of furnishing the strength required for a particular building

When we consider steel-frame buildings we meet an apparent contradiction, for though everyone knows that the steel in a building frame does not burn when the building burns, it is also [illegible]

ELECTRONS AND THE ELECTRONIC THEORY are discussed by Sir Oliver Lodge in Scientific American Supplements 1428, 1429, 1430, 1431, 1432, 1433, 1434. Price 10 cents each. For sale by Munn & Co., Inc., and all newsdealers.

edge that an unprotected steel frame will bend and collapse when it is heated red-hot. This bending of steel frames under heat is not a loss of chemical balance, but is mechanical. The steel when heated loses its stiffness, but remains chemically unchanged. This loss of mechanical balance is guarded against by covering the steel framework with substances that will protect it from heat—commonly brick, tile or cement. Even wood will serve for a time, for although the wood casing will finally burn off if the fire continues long enough, it will prevent, until it does burn off, that heating of the steel frame that destroys the rigidity of the steel and causes collapse of the building.

It should be noted, however, that the failing of steel or iron framework in a fire is merely mechanical, and that steel is thoroughly effective as a fire resistant when it does not have to support a load. We see this use of steel or iron in the tin-covered doors that have been used in factories for many years past. The metal covering of such doors (which are wood inside) may become red hot, but it does not give out because there is no mechanical strain on it. In other words, it preserves its chemical balance, and has no mechanical balance to worry about.

In trying to build a fire-proof structure it is necessary first to protect the chemical balance of the structure by using non-burnable materials, and if the structure has a steel frame, as most large modern buildings do have, to safeguard the mechanical equilibrium of the frame by protecting the frame from severe heating that would cause it to collapse. But there is in every large building a new problem due to the size of the structure and to the amount of burnable material that may be gathered in one apartment—or compartment—of the building.

In this respect there are really two problems looking merely to the safety of the building as a structure. One problem is to reduce the amount of combustible material to so small a heating power that it cannot overcome the heat protection given to the steel frame. The other problem, which arises mainly in office and apartment buildings having many separate compartments or rooms, is to build each compartment so that a chemical overturning—or fire—starting therein may be confined to that section or unit.

Generally speaking, a fire in one room or one suite of rooms in a large building will not endanger the stability of the structure itself, provided the fire can be restricted to the compartment in which it starts. Or to recur to our first idea, the heat-push due to the combustion of the contents of one room will not upset the balance of the whole structure if the push can be kept localized. If we take for an example a large office building, it is plain that the stairwells and elevator shafts become, in the event of fire, chimneys which develop an enormously powerful draft and which speed a fire to all parts of the building above the level where the fire originates. The danger to human life from this spreading of fire and smoke in an office building is the first and most serious disaster to be avoided under all circumstances.

A fire spreading by elevator shafts and stair-wells represents a magnifying of the disturbing heat-push generated in the room where the fire begins. Obviously the first step to be taken is to localize the initial push by confining the fire to the rooms where it begins, behind non-combustible doors. The next step is to limit the energy of the heat-push within the room itself, and here the same principles apply that are absolutely necessary in the efficient protection of the larger unit of the whole building.

Assuming that the particular room or series of rooms is shut off from the main passages of the building by non-burnable doors, the next step is to apply within each room the rule that everything possible shall be made of non-combustible material. This is simply the unit system of fire protection with the protection carried into subdivisions of units. The procedure applies not only to the interior finish of the room, but to the furnishings of the room.

EPICYCLIC TRAINS, which play an important part in toothed gearing, are ably described in Scientific American Supplement 1524. Price 10 cents. For sale by Munn & Co., Inc., and all newsdealers.

PORTLAND CEMENT MAKING is described in excellent articles contained in Scientific American Supplements 1433, 1465, 1466, 1510, 1511. Price 10 cents each. For sale by Munn & Co., Inc., and all newsdealers.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement

The Minority Views on the Oldfield Bill

In their excellently written report on the Oldfield Bill six of fourteen members of the House Committee on Patents have expressed their minority views on the folly of introducing compulsory licenses and of extinguishing the right of a patentee to treat license violations as patent infringements. Not only are the defects to which we have previously called attention mercilessly exposed, but others are revealed which show how hastily and how recklessly the Oldfield Bill was framed to cure 'evils' which do not exist.

In the proposed introduction of compulsory license and in the limitations intended to prevent the patentee from fixing the price at which his invention may be sold or from prescribing the manner of its use, the minority members see nothing but danger. Compulsory working clauses are to be found in many of the European statutes. Not only are the European industrial conditions different from ours, but it seems to be the consensus of opinion that the compulsory working clauses of foreign countries have not been a success and have discouraged the investment of capital in industries based on patents. If Representative Oldfield's bill were enacted into law, American inventors would be deprived of their present stimulus and would find it difficult to enlist financial support.

Even if the compulsory license principle could be successfully grafted on our patent system, the minority members of the Committee point out how impossible it would be to carry out Representative Oldfield's provisions and still do justice. So carelessly has the bill been framed that it contains no provisions to permit the intervention of a licensee in an action brought to compel the granting of a license. Hence a licensee might be kept in complete ignorance of a proceeding in the outcome of which he is vitally interested.

Equally reprehensible is the failure to deal with the situation arising from fractional or undivided interests in patent rights. The minority members point out that a patent may sometimes stand in the name of several owners. Is it sufficient to serve any one of them? Is it sufficient to pay royalties to one alone? If not, how are the other owners to be brought in and made parties?

The loose manner in which the words "patented invention" are used in the Oldfield Bill is severely criticised, and the results of the necessary construction, which a court would be compelled to place upon them, are tellingly set forth. Theoretically every claim in a patent covers a distinct invention. In a patent containing fifty claims, twenty-five may cover inventions not actually embodied in the commercial product. Since every claim embodies a patented invention, unlimited opportunities for engaging in compulsory license litigation are thus presented. This construction of the words "patented invention," however fantastic and far fetched it may seem, is obligatory. If it were not adopted the minority members fear that it would be possible to draw a patent with a hundred claims of which only one might be worked and ninety-nine with held in flagrant evasion of the provisions for compulsory license.

According to Representative Oldfield and those who side with him an invention is suppressed if it is not adequately used. What is adequate use? In a previous issue we reviewed in these columns some of the difficulties encountered in interpreting the English statute containing a similar expression. The minority members point out still other difficulties. It is hard enough in an ordinary infringement suit to determine whether or not the defendant has used the complainant's invention. The same issues would be presented in compulsory license proceedings. In other words, an application for a compulsory license involves a consideration of a patent's validity and scope, of questions that inevitably arise in every infringement suit.

Let it not be supposed that the Oldfield Bill regards the mere non-use of a patent as a sufficient ground for the granting of a compulsory license. As the minority members of the Committee show, the right of the applicant for a license is dependent upon his demonstrating that the patented invention is being withheld or suppressed for the purpose or with the result of preventing others from competing with articles made by the patentee. "This plainly is an invitation to the easy circumvention of the law by the simple expedient of assigning the patent which it is desired to suppress to someone not engaged in producing any article in competition with the patented invention."

Was it oversight or simply a drastic discrimination against the patentee that induced those responsible for the Oldfield Bill to omit any provision which compels the applicant to accept a compulsory license and pay the royalties prescribed? An enemy of corporations, on reading the bill, would conclude that some industrial octopus stands behind Oldfield. How else could he explain the circumstance that those who can bear the cost of litigation will be enabled to apply indiscriminately for licenses and to accept only those which they may get on exceptionally good terms, with the privilege of abandoning the others after having put the defendant owners to heavy expense in establishing the value of their patents? The minority members fear that the entire assets of a small firm might easily be consumed in defending such a proceeding brought by a powerful corporation.

The amendment of the original Oldfield Bill so as to bring the patent monopoly within the Sherman Law is not approved by the minority. Framed as it was in executive session, without any public hearings to ascertain the views of inventors and manufacturers, the minority members feel that it cannot be seriously considered. That the Sherman Law is amply able to prevent the misuse of the patent monopoly, the minority prove by critically considering some of the decisions handed down in causes that involved an apparent conflict between the Sherman Law and the Patent Statutes. These decisions indicate that when there is no question of the right of excluding others from using or selling an invention in the manner prescribed by the patent law, the Sherman Act applies to patentees as well as to all monopolists. Moreover, the very recent decision in the Bathtub Case demonstrated that the owners of patents are not exempt from the sweeping provisions of the Sherman anti-trust act against monopolistic combinations, and that there is no such inherent natural distinction between owners of patents and owners of unpatented staple products as to justify the application of the Sherman Law to the one class and not to the other. In a word, the proposed Oldfield recodification of our patent statutes is a brilliantly unnecessary piece of legislation, which has needlessly worried manufacturers and alarmed every business man who deals in patented articles.

Sir William White

While most of us wander in life's by ways, exerting but a vanishingly small influence on the progress of human affairs, into the lives of others is crowded such a wealth of events and activities that the task accomplished seems, to the looker on, almost superhuman. In a space of sixteen years, from 1885 to 1902, William White, who has just passed from among us, designed two hundred and fifty warships. This was but one period in a life abounding with activity. A biography of the Father of the Modern Battleship appeared in our columns only a few months ago. The reader will remember that William White, born on February 2nd, 1845, began his apprenticeship in the Royal Dockyard at Devonport at the age of fourteen, and after eight years training in the practice and science of shipbuilding, entered, in 1867 the service of the constructive department of the British Admiralty. In 1870 he became secretary of the council of construction appointed on the retirement of Sir Edward Reed, chief constructor of the Royal Navy—a post later occupied by William White himself. During these years, in addition to his connection with the Admiralty, he also held the chair of naval architecture at the Royal Naval College, Greenwich. Among his students was Admiral Bowles, who later became Chief Constructor of our Navy. To this phase of Sir William White's activity must be reckoned also the publication of the well known 'Manual of Naval Architecture.'

In 1882 William White accepted an offer from the firm of Armstrong, Mitchell & Co. and became director of their new warship building department at Newcastle-on-Tyne. He held this post for three years, during which he superintended the construction of a new shipyard at Newcastle, and constructed warships for Japan, Italy, Austria, Spain, China, and the British Admiralty. The total value of the contracts secured within these three years was about eight million dollars. During this period the Secretary of the United States Navy purchased two cruiser designs prepared by William White, and from these the "Charleston" and "Baltimore" were built.

In October, 1885, William White was appointed Director of Naval Construction and Assistant Controller of the Royal Navy. Here he continued till 1902, when failing health compelled a rest from his arduous tasks—at the age of fifty-seven he retired from government service. Two years later he was able once more to resume active work as consulting naval architect for the Cunard liner "Mauretania."

That a man of the character of Sir William White should have taken an active part in the affairs of engineering societies and institutions is a matter of course. Many were the honors bestowed upon him—the knighthood in 1895, and the fellowship in the Royal Society in 1888 alone shall be mentioned here. But the most appropriate monument to a great man is a grateful appreciation of his work, and in this the memory of Sir William White shall not be found wanting.

The Scientific American Supplement

The Scientific American Supplement was founded in 1876 for the primary purpose of describing and illustrating the more important exhibits displayed at the Philadelphia International Exposition of that year. After the Exposition had closed, it was found that the Supplement had earned for itself so great a prestige that it seemed unwise to suppress it. Accordingly, its publication was continued, and it was made a real Supplement to the Scientific American in every sense of the word. While the Scientific American has always been primarily a newspaper in which the important scientific discoveries, engineering improvements and inventions of the day were promptly and briefly discussed, the Supplement was reserved for the publication of highly important technical papers, read before learned scientific societies, and the translations from foreign publications of articles otherwise inaccessible to Americans.

The amount and character of the material thus printed is remarkable. Practically every field of science, both pure and applied, is represented. The articles themselves are penned, for the most part by the most conspicuous investigators in their respective fields. Indeed, the best scientific thought of the day has always been concentrated in the pages of the Scientific American Supplement in papers written by the most eminent chemists, engineers, physicists, physicians, biologists, and natural scientists. In that respect the publication stands probably unique among all periodicals. We would like to introduce and make thoroughly familiar to our readers some of the authors whose names appear at the head of the articles published in the Supplement, but the list is so long that space does not permit to give more than a brief selection. We see there the names of George Westinghouse, Mr. Logan Waller Page, Prof. W. D. Bancroft, Dr. Baekeland, Prof. Bernthsen, Prof. Wilhelm Ostwald, Prof. Fleming, Sir Oliver Lodge, Sir J. J. Thomson, Prof. Leonard Hill, Sir William White, Sir Robert Hadfield, and many others noted for the important share which they have had in advancing the world's knowledge and power over natural forces.

Since the papers of such distinguished men have more than an evanescent value, a printed catalogue of Scientific American Supplement articles is published from time to time, which is distributed gratuitously and which indexes some ten thousand subjects that have been discussed from all angles. A complete file of past issues of the Supplement, extending back to the year of its inception, thirty-seven years ago, is kept in stock, and copies can be supplied at any time at the published price. These files, together with the catalogue, form an unparalleled reference library within the reach of all at a nominal cost. So far as we are aware, no other scientific periodical has attempted and executed such a feat as this.

The Scientific American Supplement is supported by its subscribers. It contains no paid advertising, in which respect it again stands unique among scientific periodicals.

An "Eiffel Tower" in Buenos Aires.—Application has been made to the municipality of Buenos Aires for a 60-year concession to erect on public property the "Torre Rivadavia," similar to the Eiffel Tower in Paris. It is to be 1,067 feet high, topped by a 106-foot statue bearing a light of 1,000,000 candle-power, making the total height 1,173 feet (Eiffel, 984 feet). It is to be equipped with a wireless station, a meteorological observatory, and an immense electrical clock.

Engineering

A Fatal Sawdust Explosion.—The falling of a bolt among the cutters on a machine for grinding sawdust in a box factory at Philadelphia is stated to have caused a shower of sparks which ignited the finely divided dust and caused an explosion which injured six employees and killed one. Explosions of this character are common in coal mines and they have occasionally occurred in flour mills and other industrial establishments where inflammable dust is generated.

Curious Drydock Disaster.—During a gale a drydock at Spotstown Glasgow, was suddenly flooded by the onrush of water past the caisson gate, three of the workmen in the dock being drowned. The ship was moved from the keel blocks and she was filled with water, some of her plates being off at the time of the accident. An abnormally high tide caused the caisson to lift from its seat. A similar accident happened in one of the drydocks at the Brooklyn Navy Yard many years ago, when the caisson gate, not having been sufficiently ballasted, lifted during a high tide, the water rushing in and damaging two torpedo boats that were in the dock.

The Ingots to Blame.—At last the metallurgists, steel makers and rail users of the world are becoming thoroughly awake to the fact that the original seat of the defects which result in broken rails is the ingot. Hunt, Talbott, Hadfield and many other eminent authorities have recently shown that we cannot be sure of the quality of rails unless we are assured of the quality of the ingots. The latest paper to this effect is one by Bradley Stoughton. Our rail manufacturers are beginning to realise that they must concentrate their attention increasingly upon the furnace practice, and especially upon the ingot, if they are to turn out a reliable product.

In Touch by Wireless Across the Atlantic.—We are informed by the Hydrographic Office in New York that recently the steamship "Barbarossa" was in daily touch with the Hydrographic Office in this city by wireless throughout the whole of her voyage to the eastward across the Atlantic. Communication was maintained up to a distance of 800 miles by radio with the shore station of the Atlantic coast, when the "Barbarossa" came in touch with Crookhaven, Ireland, and the messages were transmitted back by cable. The office has arranged to keep a record of the positions of ships transmitted by radio, and the location of ice and derelicts is being sent direct to the Hydrographic Office in Europe for transmission to ships starting on the westward passage.

Vast Increase of British Navy.—According to recent dispatches the programme for the increase of the British navy this year calls for five or six battleships, the number depending upon the Austrian naval programme. The programme at present calls for five battleships, six armored cruisers, twenty destroyers, several submarines and an addition of 5,000 men to the personnel, making a total of 142,500 officers and men. The cost of this programme will be $240,000,000. The battleships will be of large size, probably 28,000 tons, and it is said they will carry either eight 16-inch guns, each firing a 2,200-pound shell, or a larger number of 15-inch guns firing an 1,800-pound shell. We think that ten 15-inch guns will be the probable armament.

Bids for Building the "Pennsylvania."—Of the three best bids for the construction of our latest battleship the "Pennsylvania"—the largest ship authorized or under construction—made by the Newport News, the New York Shipbuilding and the Fore River companies, that of the Newport News yard of $7,255,000 was the lowest, and the contract has gone to that firm. The total cost of the ship when complete with guns, armor and equipment will be $14,173,000. The "Pennsylvania" was described in a recent issue, in which her dimensions were given as 600 feet between perpendiculars, 625 feet over all, beam 97 feet, and draught 29 feet. The maximum full-load displacement will be 32,500 tons. She will be the largest, best protected and most powerful ship afloat on the day of her launch.

Steel Trains on the New Haven Road.—The two five-hour expresses daily between New York and Boston over the New York, New Haven and Hartford R.R., are now made up of new all-steel Pullmans. These cars embody heavy cast steel U-shaped ends, forming the vestibules, connected by two heavy steel girders which make it well-nigh impossible for the cars to buckle or telescope. Each train consists of four parlor cars, a combination parlor and baggage car, a diner, and an observation smoker at the rear. The drawing-room has been dispensed with in the parlor cars. The ivory-white ceilings reflect the upwardly-thrown rays from ten 100-watt tungsten lamps, each of which is in a lacquered bronze bowl reflector. Each car has two sets of storage batteries connected in multiple, which provide enough current to run the lights when stops are being made at stations, and even for ten hours independently of the charging dynamo driven by a belt from the car axle. The Garland system of ventilation does away with all drafts. This system provides for the entrance of fresh air at the front of each car and the discharge of used air through ventilators in the deck sashes of the roof.

Electricity

Dr. Acheson Honored by the Czar.—The insignia and sash of the Order of St. Anne have been presented to Dr. Edward G. Acheson by the Czar of Russia. Dr. Acheson visited Russia to address the Russian Imperial Technological Institute in order to explain the nature and use of deflocculated graphite. The order of St. Anne is one of the highest honors that can be conferred in the Russian Empire and carries with it nobility to the recipient. Dr. Acheson is now listed as a noble of the Russian Empire.

Transformers in the Lamp Sockets.—The new German method of using a miniature transformer in each lamp socket has the advantage of allowing the use of a low-voltage metallic filament lamp, for instance a 14-volt lamp, and such filaments are much stouter than the usual kind. It is also claimed that the low-volt lamp is more economical in its use of current, and besides, the lamp is from 50 to 70 per cent cheaper to make than the others. Low candle-power lamps from 3 candle-power up can now be made with thick filaments, when using 14 volts. The usual 16 candle-power lamp has two filaments side by side, so that one can break and the other holds good. Each lamp has a small transformer fitted into the socket, and the key turns off the primary coil of the transformer, so that there is no leakage current.

Making Nickel Tubes Electrolytically.—Nickel tubes and other objects are made by the new Ed. Levi process, as it allows of obtaining a thick deposit of nickel in a special plating bath. An acid solution of nickel sulphate is used, preferably as a hot bath. Nickel anodes are employed and the voltage between electrodes should not exceed 3 volts. The density of current is 2 to 3 amperes per square decimeter of surface, and even more, as it is preferable to use a high-current density in this process. A very acid bath at 10 or 15 degrees B. is recommended. The nickel thus obtained is very even and can be plated in a thick layer. Nickel is deposited in this way on an aluminum form, then the form is separated by dissolving in caustic potash or by melting. A tube is best for this form. Thus the nickel is left in the shape of a tube, and the metal is said to be very tough and malleable.

Electricity from Peat.—In a paper read before the Mechanical Engineers Society, M. Bartel brings out some ideas in the way of utilizing the great natural resources which North Germany has in the shape of extensive peat fields, so that this can be used for a good part of the steam power needed for central stations. To keep pace with coming needs in this region there will have to be erected a number of electric plants giving a total of 10,000,000 horse-power, counting 8,000,000 for the use of railroads alone. As this part of the country has but little hydraulic power, steam will be needed and peat fuel is recommended by the author. In this way the great marshes or bogs would be dried up so as to leave a large amount of land for agriculture and the like. In fact he calculates that North Germany contains enough peat to supply all the current needed in this region for as much as 250 years to come.

Electroculture by High-tension Discharge System.—A recent issue of a German electrical paper reports some successful experiments at Petrovic (near Prague) in stimulating the growth of vegetables by high-tension discharges from a network of steel wires stretched across the field at a height of twelve feet above the ground. High-frequency electrical energy was transformed up to 100,000 volts and then rectified for delivery to the network. The total power consumption for the ninety acres constituting the "plant" was two amperes at 120 volts. By turning on the current for a few hours each day—except during wet weather, and during very hot weather when the discharge treatment is useless or even injurious—the quality as well as the yield of the crops was much improved. It was concluded that a similar plant designed to take a large output of electrical energy would pay for itself during the first year of operation.

Flame Detector of Hertzian Waves.—It is found by the German scientist Leithauser that a flame will act as a detector for wireless waves. At the sending end is an induction coil giving a 0.2-inch spark and an antenna wire 5 feet long, and at the receiving end placed about 60 feet off there is mounted an antenna which connects to one electrode placed within the flame of a Bunsen burner, the second electrode being connected to ground. The first electrode consists of a platinum capsule containing carbonate of potash, and the flame keeps it at a red heat so as to melt the salt. The other electrode is a 0.04-inch copper wire placed horizontally at about 0.1 or 0.15 inch from the first. Wires lead from each to a telephone, or in other cases a galvanometer. At each wave signal sent out, there is heard a sound in the telephone. The current set up in the telephone seems to be caused by the flame acting as a current rectifier. Potash salts appear to give the best results, and both electrodes must be kept at a red heat, however a difference of temperature is needed between them, and it should be noted that the direction of the current given off by the flame combination which appears to work as a battery, depends on which of the metal pieces has the higher temperature.

Science

The Death of Lieut. Francis L. Harris.—The last survivor of the Hayes arctic expedition which went forth in search of Franklin in 1860, died in Boston in the 80th year of his age recently. He was Lieut. Francis L. Harris. Although it stayed in the Arctic about two years and suffered great hardship, the expedition did not find Franklin. After the return of the expedition Lieut. Harris enlisted in the Union Navy and fought throughout the war.

The Death of Dr. P. H. Hiss, Jr.—Dr. Philip Hanson Hiss, Jr., professor of bacteriology in the College of Physicians and Surgeons of Columbia University, died recently in New York city, after a long illness. Although only forty-five years of age Dr. Hiss had made a reputation for himself chiefly for his method of differentiating typhoid and colon bacilli, his method of isolating typhoid bacilli, his studies of the bacteriology of typhoid fever, his determinations of the relation of serum globulin and diphtheritic antitoxin, and his differentiation of pneumococcus and streptococcus and capsule staining methods. His recognition of dysentery, typhoid and allied bacilli, his researches on the bacilli of the dysentery group, and his study of the curative influence of extracts of leucocytes upon infections also deserve mention.

Water Hardness and Health.—Hardness of water, that is the amount of lime or other salts which it contains, appears to have a direct influence upon the health as the researches of Dr. H. Roemer of Berlin bring out. Dentition is much influenced, as observed in the case of school children, and examining several thousand he finds that the percentage of persons having entirely sound teeth varies from 1.3 up to 20.2 per cent, according to the degree of hardness of the water in various localities. Hard water containing lime acts favorably in this case and magnesia appears to harden the enamel. The number of young men adapted for military service also increases in regions having hard water. As to action on the blood, lime and magnesia act by their alkaline properties to strengthen the growth of children. According to this he states that soft water should be used for washing and cooking and hard water for drinking purposes.

The Turkey Buzzard and the Hummingbird in the House of Representatives.—On February 8th Mr. Akin of New York submitted the following resolution in the House of Representatives which resolution was referred to the Committee on Agriculture and ordered to be printed:

Resolved, That the Secretary of Agriculture be, and he is hereby, authorized and directed to expend not exceeding $1,000 in the purchase of six high-grade thoroughbred male turkey buzzards and ninety-nine thoroughbred humming birds, each to be examined and passed upon by Dr. A. D. Melvin, Chief of the Bureau of Animal Industry, as to soundness of limb and heart strength, in order that a test may be made as to the value of the offspring, be they gnats or fleas, for agricultural purposes, and to report to Congress whether the experiment is more valuable to the American farmer than the one now going on in this bureau where thousands of dollars have been expended in buying zebras in Africa and transporting the same to the District of Columbia, where they are joined in wedlock to Missouri mules, the offspring of which seem to be a cross between a North Dakota jack rabbit and an Australian kangaroo; and the sum of $1,000, or so much thereof as may be necessary, is hereby appropriated out of the contingent fund of the House to carry out the purposes of this resolution.

Those responsible for the printing of this absurd resolution ought to take a course in the correct appreciation of jokes.

Detroit Observatory of the University of Michigan has just issued the first installment of its "Publications," including an historical sketch of the institution by its present director, Prof. W. J. Hussey. It is, in several respects, among the most interesting observatories in America. It was built in 1854 with money raised by citizens of Detroit, whence its misleading name. (It is situated at Ann Arbor.) It was equipped at the outset with a 12¼-inch refractor by Fitz of New York, still in use—which was, when built, the third largest refractor in the world, and the first large telescope constructed entirely in the United States. The observatory is almost unrivaled among American institutions in the number of distinguished astronomers who have been connected with it, as directors, members of the staff or students. A picturesque chapter in the history of the observatory relates to the discovery of 22 minor planets, between the years 1863 and 1877, by Prof. Watson. One of these, Aethra, has been lost, no observations of it having been obtained since those made at the time of its discovery in 1873, which were not sufficient for a satisfactory determination of its orbit. "The planets discovered by Watson are endowed," the discoverer left a sum of money with the National Academy of Sciences to be used in preparing and publishing tables for these bodies, and the first installment appeared in 1910. Since 1911 the director of Detroit Observatory has also been director of the Observatory of La Plata, in Argentina, dividing his time between the two institutions. What with the observatory's misplaced name, Watson's "endowed planets, and Hussey's shuttling between antipodean institutions, the history of Detroit Observatory has certainly been tinged with bizarrerie.

The Curtiss Military Biplane

Description of the New Curtiss Tractor Aeroplane for Army Use

By Stanley Yale Beach

THE new Curtiss biplane illustrated herewith has been produced in fulfillment of the specifications for army aeroplanes issued by the Government early this year. These requirements have been published in the SUPPLEMENT No. 1940 and a résumé of them was given in our last issue. The chief requirements are that the machine must carry a load of some 600 pounds during a 4-hour flight; that it must rise at the rate of 200 feet a minute and that it must have a maximum speed not exceeding 65 miles an hour.

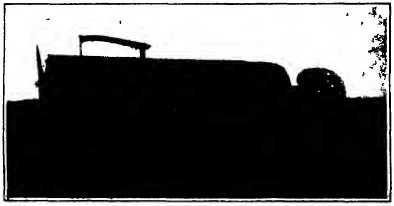
To fulfill these requirements Curtiss has produced a rather large biplane having a spread of 37 feet 4 inches for the upper plane and a total over all width of 38 feet 4 inches as against a length of 24 feet. The chord of each plane is 61 inches and their spacing apart 60. The weight of the machine complete is 1,050 pounds.

As will be noticed from the photographs this new machine is radically different from the former Curtiss military biplane. The use of a covered fuselage is in partial fulfillment of the army requirements, and this, together with the placing of the power plant and propeller in front follows European practice. The complete covering of the fuselage to reduce head resistance and the arranging of the radiator and motor in front, with a bonnet similar to that used on automobiles is distinctly novel as regards a Curtiss machine. The wings are made up each in one piece instead of in sections as heretofore and they are so set that their front and rear edges form a slight dihedral angle extending backward from front to rear. This form tends to give the machine a certain degree of inherent fore-and-aft stability. The unit construction of each wing and the method of fitting the tail, rudder, etc., make it possible to take apart the machine or put it together again in less than half an hour. One of our illustrations shows the four wings placed beside the body when the machine is to be towed over the road.

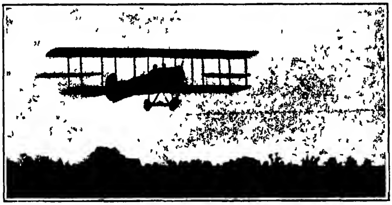
The three-wheeled chassis has a maximum width of 65 inches reduced to 42 inches at the fuselage while the tread is 56 inches. The body is wide enough for two men to be seated in it comfortably and there is a panel removable from the lower plane on each side of the body to allow the occupants to look directly downward if they so desire.

Each aviator has a separate control wheel so that either man or both together can drive the machine. A 40-gallon gasoline tank is placed under the seats, but for running the aeroplane a small 2-gallon tank on the dashboard is kept filled by means of a pump driven from the engine. A glass plate in the face of this tank makes it possible to see at all times the amount of gasoline in the tank and whether or not the pump is working. Should the supply from the main tank cease by throwing a small lever and giving a few strokes of a hand air pump the gasoline will flow from the main tank by means of air pressure developed therein. Another convenience is the carrying off of the oil and smoke from the engine below the body by means of pipes. The up-curved dash in front of the aviators directs the blast of air from the propeller above their heads, also. Although this is the largest machine thus far built by Curtiss, it can be knocked down and packed in three small boxes in short order. To collapse any of the four wings completely so that they will fill a space but six inches wide it is only necessary to remove four bolts.

The new method of wiring and bracing used in the fuselage does not require any holes to be plugged in the main longitudinals, which are made of white spruce and which taper from the front to the rear. The body is so light that it supports itself a light skid being placed under the tail for protection only in making a bad landing. The head resistance of this machine has been reduced so that the machine is as fast as any of the lighter bodyless types now used by the army. It is therefore a distinct advance as far as American military aeroplanes are concerned.



Machine with wings placed beside the body for towing over the road.



Front view of the new tractor biplane in flight, showing comfortable seating of the aviators.

Side view of the latest Curtiss military biplane.

Note dihedral angle of wings as viewed from above, the ailerons, the three-bladed propeller, covered fuselage and fan tail.

A Canadian Arctic Expedition

VILHJALMUR STEFANSSON, well known for his explorations along the Arctic shores of British America and for his discovery of blond Eskimos, has for some time been planning an expedition to seek for new lands in the vast unexplored region lying to the north of the Beaufort Sea and the Parry Archipelago. He recently secured the financial backing of the American Museum of Natural History, the National Geographic Society, and the Harvard Travelers' Club; but shortly afterward was invited by the Canadian government to undertake the journey under its auspices and at its expense. He has accordingly been released by the three American societies and the expedition will sail under the British flag. Stefansson is a Canadian by birth, but was educated in the United States.

The expedition is expected to sail from Esquimault, B. C., the latter part of May on the whaler "Karluk," just purchased for this purpose, and to spend about three and a half years in the Arctic. Dr. R. M. Anderson is to be second in command, and the scientific staff will probably consist chiefly of Canadians. The region to be explored is the largest stretch of completely unknown sea or land in the northern hemisphere. Certain peculiarities of the tides seem to indicate that it contains extensive land areas. On the eastern border of this region is the supposed location of Crocker Land, which was sighted by Peary on his journey to the pole, and is to be sought by Macmillan's forthcoming "Crocker Land Expedition." It should also be noted that Amundsen's projected drift across the North Polar Basin will probably carry him into this unknown area.

Stefansson hopes to land at Prince Patrick Island next September and establish his main base at Land's End. The ship is to leave him here, return to civilization and thereafter to make yearly visits to the base. Of course any such programme is liable to be more or less modified by ice conditions. From Land's End the party expects to make sledging journeys in various directions over as much as possible of the million square miles that are now a blank on the map.

The expedition will be equipped with a powerful wireless telegraph outfit, and it is hoped that the base station will thus be kept in constant communication with the world. This ought not to be difficult since the Canadian government is now establishing a chain of wireless stations in the far north of British America, including one at Herschell Island, at the mouth of the Mackenzie River. It is also proposed to carry a wireless outfit on the sledge in order to keep the explorers in touch with their base. A moving picture machine is to be included in the equipment of the expedition.

Court Decides Against the Taggart Dental Inlay Patent

MUCH interest is taken by dentists in the decision of the Court of Appeals of the District of Columbia voiding the Taggart patent, No. 872,978 of December 3rd, 1907, upon a divisional application filed July 12th, 1907, of original application filed January 12th, 1907. This decision, the opinion in which was rendered by Mr. Justice Robb, reverses the decision of the Supreme Court of the District of Columbia, which decision sustained the Taggart patent. Defense was made that the invention had prior to Dr. Taggart's invention been taught, used and operated, at least two years before the filing of the Taggart application for patent. The Court said that it was fully persuaded that the evidence shows beyond a reasonable doubt that for many years prior to the filing of the application for patent the process of making patterns and molds for dental inlays and the like, as expressed in the claims, had been publicly practised upon many occasions, and that it was of no possible consequence that by the use of Dr. Taggart's machine, gold inlays and the like might be produced more cheaply and rapidly than they were produced by dentists who had testified in the case. The Court goes on to say that the art of producing metal castings by means of a mold formed of a wax pattern is very old, was practised by the ancient Greeks and Romans, extensively used in the middle ages for producing statuary, and is known as the *Cire perdu* or "lost wax" process.

A Chair of Sericulture has been created in the scientific department of the University of Lyon, France, as a part of the general instruction in applied sociology. Funds for the payment of a professor and an assistant have been raised by the local chamber of commerce, as one means toward maintaining the supremacy of Lyon in the silk industries of Europe.

The Growth of a Great Navy

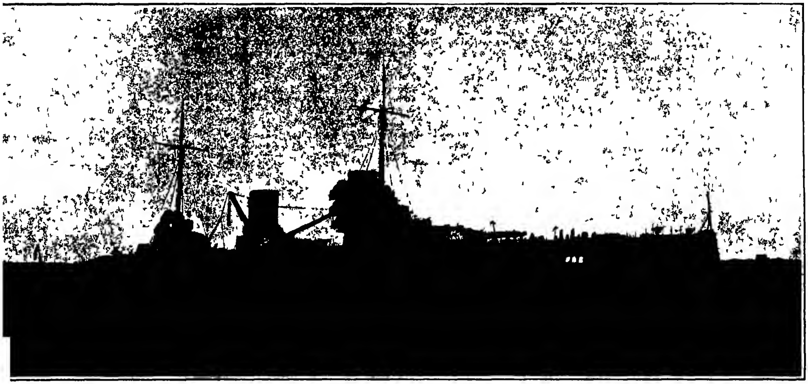
How Germany Has Advanced to the Second Position

By Percival A Hislam

THERE has been a vast number of changes in the last few years in everything that affects naval power, but none is more remarkable than the rise of Germany from a position of absolute insignificance into that of the world's second sea power The work has been accomplished in the face of extraordinary natural difficulties, for not only are the German people essentially agrarian, but their harbors on the open seacoast have had literally to be dug out of the mud, and she must always remain under the heaviest of Nature's handicaps, for the island of Great Britain stretches like a great breakwater between Germany and the ocean

Considering the part Germany plays to-day in the naval politics of the world—she has 11 completed dreadnoughts to England's 18, and to America's 8—it is difficult to realize that her naval expenditure did not reach $25,000,000 until 1897, and that the fifty million dollar mark was not passed until ten years ago. From 1908 onward her naval expenditure has totaled well under a half of Great Britain's and yet in that period she has launched 18 armored ships as compared with that nation's 22, and with the 10 of the United States. The German fleet is largely manned on the conscript system and it is this, of course which accounts very largely for the cheapness of her naval service

To realize the truly marvelous growth of German naval strength it is not necessary to go back more than ten years. In 1902 her naval expenditure was $50,225,000 and it has increased so rapidly that no less than $113,047,200 is being spent this year The number of officers and men voted for the fleet in 1902 was 31,500 For the current year the figure is 62,670, and under the recently adopted amendment to the navy law of 1900 the personnel is to be increased to 101,500 by 1920 For two years after England completed the "Dreadnought" (in 1906) Germany was passing into service battleships of 13,040 tons, more than 30 per cent short of her displacement, but the armored



Length, 610¼ feet. **Beam,** 96 feet **Displacement,** 22,640 tons. **Speed on trial,** 29 knots **Armament,** ten 11-inch twelve 5.9-inch twelve 3.4-inch four torpedo tubes

The latest German dreadnought, "Kaiser."

ships launched for Germany from 1900 onward have actually exceeded in average displacement the vessels launched for the British navy. It has been truly said that a battle fleet is not made in a shipbuilding yard or alongside a dockyard wall, but on the high seas, and if the German fleet be measured on this basis, its progress will be found no less striking. In 1902 the "High Sea Fleet" consisted of 8 battleships, 2 armored cruisers, and 22 destroyers. To-day it consists of 18 battleships, 4 armored cruisers, 12 small cruisers and 66 destroyers, and by 1914 it is to be increased (under the provisions of the recent amendment to the navy law) to 25 battleships, 8 battle and armored cruisers, 18 small cruisers, 99 destroyers, and 54 submarines, all of which will be permanently in full commission.

Naturally, the rise of Germany at sea is felt much more keenly in England than in any other country, if only because a distance of no more than 300 miles separates the principal German naval base of Wilhelmshaven from the English North Sea coast. Whether Germany hopes some day to become the world's principal naval power (and the Kaiser has said, "The trident of Neptune must be in our fist," and "Our future lies on the water") is a political matter that cannot be discussed here, but she has at any rate made such progress in that direction that since 1904 Great Britain has been compelled, in order to preserve her superiority in her home seas, to withdraw 19 battleships from foreign stations (14 from the Mediterranean and 5 from the Pacific) and to concentrate practically the whole of her resources around her shores. The extent to which Germany has actually improved her position is shown very strikingly in the following comparison between her fleet and the British in 1904 and at the present time in the principal classes of ships, excluding in all cases vessels launched over ten years.

	1904		1912	
	Britain	Germany	Britain	Germany
Battleships	30	10	27	18
Battle cruisers			5	3
Armored cruisers	19	4	21	6
Protected cruisers	37	17	15	22
Destroyers	120	77	107	88

When the original dreadnought was laid down in 1905 it was claimed in England that the new type of ship would not only strengthen her position very greatly against other important naval powers, but that smaller nations with pretensions to a fleet would be quite driven out of business. This is very far from being the actual result. Some of the minor nations that had not laid down a battleship for a quarter of a century or thereabout are now engaged in more or less ambitious dreadnought programmes, these including Brazil, Argentine, Chili, Turkey and Spain. So far as Germany was concerned, it enabled her to start afresh with a clean slate, and although it is true that the appearance of the "Dreadnought" paralyzed the shipyards of Europe for nearly two years, they were merely preparing themselves properly for the struggle before they started on it. The result is that while England completed seven dreadnoughts before Germany completed one, the latter nation has completed 11 since 1908 to England's 11.

Again, until the "Dreadnought" appeared Germany had been content with comparatively feeble ships. The battleships she launched between 1892 and 1901 carried nothing larger than the 9.4-inch gun and the ships of the "Deutschland" class, the last of Germany's pre-dreadnoughts, displaced only 13,040 tons as compared with the 16,500 tons of the British "Lord Nelsons," and the 16,000 of the "New Hampshires." The first American dreadnoughts were no larger than the "New Hampshires," and the step between the "Lord Nelson" and the "Dreadnought" was only 1,400 tons, but Germany jumped from the 13,040 tons of the "Deutschlands" to the 18,000 of the "Nassaus," an advance of 42 per cent. This phase of German progress is shown in the following table which gives the average tonnage of battleships launched in successive years.

	American	British	German
1905	14,800	16,350	11,040
1906	16,000	16,966	13,040
1907		18,600	
1908	17,333	19,250	18,000
1909	20,012	19,575	22,440
1910	21,825	20,833	22,440
1911	26,000	22,940	24,110

Thus while American designs have gained and kept a considerable lead over both nations' ships, those of Germany have compared with British vessels, risen from an inferiority of 1,310 tons in 1905 to a superiority of 1,170 tons in 1911. On the other hand, however, German designers do not seem to have the knack of converting tonnage into fighting power. Their 24,110-ton ships of the "Kaiser" class mount only ten 12.2-inch guns in their main battery, representing a broadside fire (over a limited angle) of 9,810 pounds. The corresponding British ships have ten 13.5-inch on the center line, with a broadside of 12,500 pounds, while the American "Wyomings" have a broadside of 10,440 pounds, and the "New Yorks," 14,000 pounds. The German vessels have a large anti torpedo battery—fourteen 5.9-inch and fourteen 3.4-inch, as compared with twenty-one 5-inch in the American, and sixteen 4-inch in the British ships, but while a battleship is, of course, a compromise, the battle guns of the German ships of the "Kaiser" class give 407 pounds of broadside for every 1,000 tons displacement as compared with 529 pounds in the British "King George" class and 518 pounds in the "New York."

The German navy now comprises 8 battleships and 3 cruisers of the dreadnought type in service and 9 battleships and 3 cruisers in various stages of construction. The four earliest battleships, "Nassau," "Westfalen," "Rheinland," and "Posen," were launched in 1908. They displace 18,600 tons, and with reciprocating engines of 20,000 horse-power have steamed from 20.1 to 21.4 knots, while their armament consists of twelve 11-inch, twelve 5.9-inch and sixteen 3.4-inch guns. They were followed by the "Helgoland," "Thüringen," "Ostfriesland," and "Oldenburg," launched in 1909-10, and displacing 22,440 tons. Their armament consists of twelve 12.2-inch, fourteen 5.9-inch, and fourteen 3.4-inch guns, and their speeds (with 28,000 horse-power) range from 20.8 to 21.6 knots. These eight ships have their big guns arranged very inefficiently, there being only two turrets on the center line and two on either beam, so that only eight guns bear on the broadside. Thus it happens that the broadside fire of the "Nassau" (18,000 tons) is only 6,080 pounds, while that of the "Michigan" (16,000 tons) is 6,080 pounds. The main armor belt of the first four German ships is 9¾ inches, and of the latter four, 10¾ inches thick, reduced in each case to 6 inches forward and 4 inches aft.

The battleships under construction fall into two groups. The first comprises the "Kaiser," "Friedrich der Grosse" (both under trial), "Kaiserin," "König Albert" and "Prinzregent Luitpold," having a displacement of 24,110 tons, a designed speed of 20 knots (the "Kaiser" has made over 23 in a spurt on trial), and an armament of ten 12.2-inch, fourteen 5.9-inch, and fourteen 3.4-inch guns. The main weapons are in five turrets, of which three are on the middle line, one forward and two aft, the inner of the after pair being superposed to bear astern. The other two turrets are *en échelon* amidships, so that there is nominally a full broadside. The angle covered by ten guns is, however, necessarily small (about 30 degrees), and while the armor belt is increased to 12 inches, it does not appear that very good value has been obtained for the increase of 1,800 tons over the preceding group. The "Kaisers" are the first German battleships driven by turbines, the horse-power being 28,000.

Of the later battleships very little is known save that the authorities are having a good deal of trouble over their armament. The vessels concerned are known as the "Ersatz Weissenburg," "Ersatz Kurfurst," "Friedrich Wilhelm," "Ersatz Brandenburg" and "S." It was at first intended to give them either thirteen or fourteen 12.2-inch guns, but this would have involved triple turrets, and these have, in Germany, proved a failure. As an alternative, ten 14-inch were decided on, but here again, while Krupps have had a 14-inch on hand for a long time, they have been unable to produce a mounting that satisfies the requirements of the Admiralty officials. There is a possibility of twelve 12.2-inch in six center line turrets being adopted as a solution.

America has already made the acquaintance of German battle-cruisers, the "Von der Tann" having visited the southern continent in 1910-11, while the "Moltke" was at New York recently. The former is practically a copy of the British "Indefatigable," having eight 11-inch in four turrets, two on the center line and two *échelonned*, well apart longitudinally, amidships. Her torpedo defense battery consists of ten 5.9-inch and sixteen 3.4-inch guns, while her best recorded speed is 28 knots with turbines of 44,000 designed horse-power. Her displacement is 19,100 tons. The "Moltke," her successor in order of building, displaces 22,640 tons and carries an additional pair of 11-inch guns in a superposed turret aft. She has made 29.7 knots with turbines developing 80,000 horse-power. The recently completed "Goeben" is similar to the "Moltke," but has been credited with a maximum speed of 32 knots. Experience shows, however, that German newspaper reports always exaggerate the speed of their new ships.

Comparative Dreadnought Strength.

	Complete	Building*	Battle Guns in Completed Ships. Total	Broadside.
Britain	18	18	170	156
Germany	11	12	124	98
United States	8	5	80	80
Japan	2	5	24	16
Brazil	2	1	24	20
Italy	1	7	12	12
Austria	1	8	12	12

* Including those provided for in 1912.

It is understood that the last battle-cruiser to be launched, the "Seydlitz," will carry ten 12.2-inch on a displacement of 27,000 tons, but of the remaining vessels, the "K" and the "Ersatz Kaiserin Augusta," of the 1911 and 1912 programmes, nothing definite is known.

No other nation has yet completed a ship of the all-big-gun type.

The Ambrose Channel as Measured by the Panama Canal

When we place two objects side by side for comparison, we may be trying either to magnify the superiority of the one or the inferiority of the other, or again, we may be merely using one as a standard by which to measure the other. It is with this last impartial and dispassionate purpose in view that we have placed some figures relating to the Ambrose Channel beside similar figures relating to the Panama Canal.

When we learned that the broad ship channel cut through the shoals of New York's lower bay was 96 per cent completed, that nearly sixty-five million cubic yards had been removed from it, and that some five million yards were still to be dredged up, we knew that we had a large quantity to deal with, but how large, it was difficult to grasp without using a bigger unit of measure. After searching about for a suitable yardstick, we were quite as astonished as our readers probably will be, to find that the Panama Canal is by no means too large a measure for the purpose. The estimated total excavation of the Panama Canal will amount to about two hundred and ten million cubic yards, or almost exactly three times that of the Ambrose Channel.

To show what this amount of material means in terms of units that are still more familiar to us, we have pictured in the front page illustration two pyramids similar in form, one made of the material excavated from the Ambrose Channel and the other from material excavated from the Panama Canal. Taking the smaller pyramid as 750 feet high, or just large enough to reach to the top of the Woolworth Building, the tallest office building in the world, the base of pyramid would be 2,750 feet square, that is, each side would have a length of eleven common street blocks.

A similar heap of dirt and rock from the Panama Canal would make a pyramid only 1,090 feet high, overtopping the Eiffel tower by something like 100 feet, while the base would measure 4,000 feet square.

How could a work of such great magnitude at our very door have escaped with so little comment? Can it be that things look larger and more important in proportion to their distance? No. This distortion of mental perspective is apparent, not real. There is no doubt that were the work not covered by a screen of water, it would receive great attention and even exaggerated importance. If the same excavation were made in New York city, it would cut a swath nearly as wide as Central Park, and stretching from Canal Street to 125th Street, and about 15 feet deep. But for the very reason that the channel has been dug under water, it is not nearly so important or difficult an engineering undertaking as that of the Panama Canal. Excavation with dredges is far more economical than excavation with steam shovels. The Ambrose Channel was started eleven years ago, and is now practically completed, and yet only four dredges at a time have been used on it, and these dredges were manned by 236 men altogether. At present only two dredges are used in completing the work. On the other hand, the excavation at the Isthmus of Panama has required the services of a veritable army of men. Thirty-five thousand men are now employed. As a matter of fact, what is left to be done in the way of cleaning up the Panama Canal will be accomplished by means of dredges after the canal is open to navigation, because this form of excavation is so much more economical and speedy.

Our front page illustration shows what an enormous load a single dredge will carry. The dredge is provided with two bins, each holding 1,400 cubic yards. To transport 2,800 cubic yards on land would require a train a mile in length, or, as shown in the illustration, four trains, each a quarter of a mile in length. These powerful suction dredges will take on a full load in less than three hours, then go out to deep water, drop the load, and return within two or three hours, depending upon whether their station is near the outer or the inner end of the channel. The load that is taken on is not, as one might suppose, a very fluid mixture of sand or mud and water. Of course, the sand is moist, but it is practically a solid load free from water. The material in the bins, unless it is mud, is so hard that one may walk upon the load without sinking in. As has been explained to our readers before, the material is sucked from the bottom through two pipes, one on each side of the hull, 20 inches in diameter, and provided with a drag at the lower end. The mixture of sand or mud and water is pumped up by powerful centrifugal pumps and delivered into the bins which, after filling, permit the water to overflow while the solids

settle. Thus the bins gradually fill up with the sediment. Mud settles slowly, and much of it is carried off with the overflow, so that when mud is being excavated it takes much longer to fill the bins.

At present practically all the work is completed except for a few stone piles, and for some excavation still to be done along the southern edge of the channel. The stone piles, by the way, are rather interesting. A number of years ago, when harbor regulations were not strictly enforced, it was quite the common thing to dump loads of stone in the lower bay. Many of these have been encountered in excavating the Ambrose Channel. The drags of the suction pipes have openings in them, measuring 7 inches by 8 inches, and will suck up anything of that size, be it stone or iron. However, most of the stones in the stone pile are too large to pass through the drag. They could be removed by using bucket dredges, but a simpler method was evolved, i. e., to bury the stones where they lay. To do this holes from ten to twenty feet deep are dredged around two sides of the stone piles, and then the survey boat with its water jets loosens the pile of stones, letting them fall into the grave dug for them.

The dredges are capable of excavating to a depth of sixty feet. The depth of the Ambrose Channel, however, is 40 feet below mean low water. The width of the channel, as we have stated before, is 2,000 feet, and the banks at each side have a 10 per cent slope.

The importance of this channel in terms of the tonnage of shipping that passes through it looms very large indeed. It has been estimated that for the first few years, the total tonnage of shipping passing through the Panama Canal will not greatly exceed ten million per annum. In 1920 it will probably reach thirteen million. Just how much shipping passes up the Ambrose Channel, it is difficult to determine. A record is kept of foreign vessels entering and clearing the port of New York, but no record is kept of coastwise shipping. The tonnage of shipping engaged in foreign trade amounts annually to about twenty seven million and practically all of it comes up through the Ambrose Channel. The coastwise tonnage is considerably more than this, but how much more no one can state definitely. For this reason we have left it out of consideration in our comparison, and have shown a single ship of ten million tonnage capacity representing the shipping that will pass through the Panama Canal and a twenty-seven million ton ship representing the foreign shipping passing up through the Ambrose Channel.

It is a pity that a waterway of such great importance should have no visible banks. Passengers who go through the Panama Canal will ever praise the engineers who carried that great work to completion, as they see the enormous cut of Culebra, the huge Gatun dam, and the massive concrete locks. But the far greater number of passengers who take the trip through Ambrose Channel to or from New York city will remain perfectly oblivious to the magnitude of the submerged canal beneath them, and to the long years of tedious work spent upon it by devoted engineers.

The Current Supplement

IN an article on Modern Microscopical Optics C. Metz, in this week's issue of the SUPPLEMENT discusses the limitations of the microscope, and the refinements in its optical system introduced by modern practice. The English correspondent of the SCIENTIFIC AMERICAN describes a remarkable aerial ropeway for tourists' service in the Tyrolese mountains.—An important article dealing with Methods of Fire Prevention tells us of the excellent work done by the British authorities in this direction.—Dr. R. C. Benner tells us "Why Smoke is an Industrial Nuisance."—"How to Make an Electroscope" is the title of an article by C. E. Benham.—Mr. John Jay Ide, familiar to our readers as the author of a number of articles on the principal types of aeroplanes, describes for us the Morane-Saulnier monoplane, the holder of the world's height record.—Prof. H. C. Jones of Johns Hopkins University writes on "Electricity and Chemical Action," a subject which he is peculiarly qualified to treat.—E. S. King investigates the question, whether interstellar space contains a medium which absorbs light.

Parcel Post Hampers

THE interest in parcel post appliances will be heightened by the report that Postmaster-General Hitchcock has made a contract for 6,000 hampers to be used in the carrying of parcel post packages. These hampers are intended partly for experimental purposes and are made to nest. They are constructed of canvas and some metal, as well as of wood and fiber, making light construction. It is reported that hampers which can be collapsed have been found in most cases too fragile so that none of the type have been purchased as yet. Many forms of collapsible containers might be developed which would not be open to the objection referred to.

Correspondence

[The editors are not responsible for statements made in the correspondence column. Anonymous communications cannot be considered, but the names of correspondents will be withheld when so desired.]

Spring Wheels

To the Editor of the SCIENTIFIC AMERICAN:

Referring to the letter in your issue of February 1st entitled "Fallacy of the Spring Wheel," Mr. Fischer states that the spring wheel will never become a practical success, his reason being that the springs in the wheel must undergo so many more flexures than the elliptical springs of the car.

This is of course true of a great number of spring wheels, but the obvious answer is that if the flexures of the springs in the wheel are in excess of the elliptical springs, the springs must be so placed in the wheel that no flexures occur in excess of the flexures of the elliptical springs.

New York city. HARRY E. SIPE.

The Bow Rudder

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of January 25th, answering the letter of A. H. Kiehl, you make the following statement: "The bow rudder is in use on special types of vessels, particularly on ferryboats, the practice being common in American harbors."

All of the ferryboats on the Atlantic coast of which I have record, are steered entirely by the after rudder, the forward rudder being locked, thereby losing the function of a rudder, in fact the forward rudder can be controlled only from the after pilot house.

I believe that under certain common conditions of current, the bow rudder could be used with success, but I have yet to see one in operation.

Princeton, N. J. ROSWELL DAVIS.

Position of Projectiles in Flight

To the Editor of the SCIENTIFIC AMERICAN:

"The Flight of Projectiles." *Re* article of Sidney Ballou in your issue of December 21st, 1912, page 581.

His second paragraph is as follows: "If a projectile rotated on an axis absolutely identical with its trajectory, the criticism would be sound, but it is just the slight departure from this condition that causes the drift. The moment the projectile leaves the gun, the force of gravity begins to pull it away from the path of the axis of its rotation, and this slight deviation is enough to make the analogy of the baseball applicable."

It might be well for the writer to point out the analogy referred to, especially since the drifts of a baseball and of a bullet are in opposite directions as pointed out by Twining and especially since Twining states that the causes of the two drifts are entirely distinct and different, in other words, that there is no analogy whatever.

Red Deer, Alberta. C. C. GRANT, M.D.

The Nature of the Patent Monopoly

To the Editor of the SCIENTIFIC AMERICAN:

Regarding the proposed legislation for eradication of the monopoly element from our patent laws.

Would it not be well to consider with exceeding care the matter of this alleged monopoly element, and to demonstrate conclusively its existence, before moving to eradicate it?

While in a general way it might be admitted by some that the inventor is a producer, there appears to be no intelligent understanding of the fundamentals of this so important subject, and the general opinion appears to be that in granting a patent to an inventor, society confers upon the latter a favor, a benevolence, and at the expense of society, for which gratuitous gift the inventor is obligated to society, as, for instance, he would be should he receive free a valuable franchise, by means of which franchise he might live in idle luxury at the expense of society. In short, the inventor is considered, whatever attitude toward him be professed, a privileged seeker, a delver into the "pork barrel," a monopolist, and a blackmailing grafter.

It is denied that the inventor is or can be a producer, he is considered merely a forestaller, an appropriator of natural laws in justice free to all, for that no man can produce by mental exercise alone.

This inventor, who may be without hands or feet, says to society, after sitting for years in exhaustive thought, "I have produced a mechanical design which, expressed materially in the form of a machine, will save the labor of a thousand men, enriching society by the labor saved. What will you give me to disclose it, and how will you guarantee payment?"

Society at present replies: "In the first place, you are a liar, you have produced nothing, for you have neither hands nor feet to produce with. Secondly, you are a thief, because you have appropriated and hold secret possession of our natural rights, but, as we know no means by which we may forcibly dispossess you and recover these our rights, and as we greatly desire possession of them, we will agree to pay your blackmailing claim, by granting you a patent right upon the design."

But, if the inventor cannot produce without limbs, how can he steal without them, and what thing economically has he stolen from society?

If all the wheat or cotton be gathered into the possession of a Patton or a Sully, how can monopoly result from such concentration, the wheat or cotton being a labor product and therefore property? How can more than temporary inconvenience result, provided the land from which the wheat or cotton was produced be still accessible to society for the production of a further supply of the desired product?

Thought applied to language produces word combinations or literary designs for the expression of opinions or ideas. Unless title to *language* be conferred upon an individual, so that he alone may produce literary designs, how can monopoly result from any individual possession of copyrights on these literary designs, which rights concern a labor product?

Thought, applied to the laws of mechanics, produces mechanical designs, which expressed materially are valuable to society. Unless title to the *laws of mechanics* be conferred upon an individual, so that he alone may produce mechanical designs, how can monopoly result from individual possession of patent rights on these mechanical designs, which patent rights concern a labor product?

A chemist burns the midnight oil in useful research for fifty years while his fellows carouse. Feeling his energies weaken, he writes the results (in a few hours perhaps) of his years of study, copyrights and rests from labor upon the sale of his book. There are many—even millions of people sufficiently hardy to deny that this writer is a producer, and to assert the equal right of the public to publish and sell this man's book without payment to him.

The inventor, whose is undoubtedly the most exhaustively consuming and poorly paid of labor, he being well-nigh universally a loser physically and financially, produces his mechanical design by years of conscientious, grinding, slavish mental toil and financial expenditure, while the public idly await his product, whereupon these latter, too lazy to produce their own designs, or too graftingly dishonest to acquire them by purchase, proceed to slanderously declare him a grafter and to actually demand equal rights with him in the use of his product.

I must deny that the inventor is a grafter, and that a patent monopoly ever existed or is possible of existence while the basic laws of mechanics are maintained freely accessible to society for the production of mechanical designs.

If Congress, therefore, in well-intentioned ignorance, or at the behest of selfish interests, legislates away from the inventor his property rights into the hands of non-producers, Congress will be guilty not alone of confiscation, but of the very worst sort, because confined to a particular class.

It will discourage unto death the inventive art, the most useful of arts, and when all too late, society will realize that in thus socializing the product of the inventor's toil, greed has at last burst the bag.

Newark, N. J. J. H. RUSBY.

"Snow-rollers"

To the Editor of the SCIENTIFIC AMERICAN:

The little article "Wind-rolled Snowballs" in your issue of March 1st is an interesting contribution to a subject with which meteorologists are tolerably familiar, but apparently the scientific world at large is not. Snowballs of the character described are known technically as "snow-rollers." (See the Supplement to the Century Dictionary.) It is likely that some of your readers will be glad to be referred to further literature on the subject.

The most extensive account of snow-rollers in the English language is that given in the *Quarterly Journal of the Royal Meteorological Society*, vol. 31, 1905, pages 87 to 96. This is mainly a compilation of accounts of the phenomenon previously published in scientific books and journals, and is illustrated. Some of these accounts appeared in the *Monthly Weather Review* (published by the U. S. Weather Bureau).

Probably the most important contribution to the subject of snow-rollers is the article "Schneewalzen" by Rudolf Meyer in *Korrespondenzblatt des Naturforscher-Vereins zu Riga*, vol. 52, 1909. This gives a list and analysis of all cases known to the writer between the years 1808 and 1909, and is accompanied by a bibliography which lists 45 previous papers on the subject, in several languages.

Snow-rollers were observed in Morris County, N. J., in January 1809 by Rev. D. A. Clark, when it is stated that "the whole landscape was covered with snow-balls, differing in size from that of a lady's muff to the diameter of 2½ or 3 feet, hollow at each end to almost the very center, and all as true as so many logs shaped in a lathe."

C. FITZHUGH TALMAN,

Washington, D. C.

"Uncle Sam's" Appraisers of Merchandise

How Imported Goods Are Examined by Experts to Determine the Duties They Should Pay

PERSONAL liberty in the United States is so complete that we scarcely realize there is a powerful central government to watch over our destinies and make us comport ourselves with proper regard for the rights of citizens in our neighboring States. Frequently an American's first real contact with Federal power comes on his return from a trip abroad, when he is advised that he must pay duty on goods that he has brought with him. He may have looked with contempt on the poor foreigner who must submit to the pettifoggery of an officious government, and he may be returning with a smug "better than thou" attitude only to receive a rude shock to his complacency as the customs officials board the vessel and make him swear out a statement of his dutiable personal effects. Then no matter if he does consider it an invasion of his rights as a freeborn American citizen, he must submit to having his trunk opened, and searched more or less perfunctorily, to make sure that he has not perjured himself. He may even be called aside to answer searching questions about a certain piece of jewelry. Now, how did Uncle Sam know that he had that trinket? For the first time he is aware of a spy system, not unlike that of Russia, which reaches out beyond our shores to foreign lands and keeps track of the purchases of the American tourists. Despite the humiliation of being treated as a smuggler he cannot help but feel a great respect for the omniscience of a government whose existence he barely realized up to that moment.

Although examination of travelers' baggage is the most troublesome work that the Custom House has to deal with, it is a paltry business compared with the collection of duties on general merchandise. The total amount of duties collected for the year ending June 30th, 1912, on articles entered for consumption was $304,[illegible]. Just how much of this came from the traveler is not reported, but obviously it was a small percentage, and it is equally obvious that the cost per dollar of collecting this duty must have been very great as compared with that on general merchandise. And yet, despite the far greater attention to personal baggage, smuggling still continues among tourists, especially those of the gentler sex, who display remarkable ingenuity in concealing their dutiable goods. One customs official hopelessly admitted that "women are born smugglers, and we cannot hope ever to suppress them."

As for general merchandise, the opportunities for smuggling are so remote, the co-operation between the Government and the importers themselves is so complete, and the penalty for smuggling is so severe as compared with the reward it offers, that practically no goods enter the country without paying duty. Take diamonds, for instance, which one would suppose could very readily be introduced into the country because their value per size is so enormous. Not only does the Government keep track of purchasers of diamonds abroad, but the dealers do as well, and they are constantly on the lookout for smuggled stones, realizing that it is to their own interest to report any stones introduced without paying the required tariff. Furthermore, to make it unprofitable to smuggle the stones into the country, the tariff on them was reduced several years ago from 25 per cent to 10 per cent.

Some idea of the enormous amount of work involved in keeping track of the goods that enter this country may be obtained by a visit to the Appraisers' Stores on the lower west side of New York. The building is ten stories high and takes up an entire block, while across the street is an annex of no mean size. In these buildings at least 10 per cent of everything that comes into New York from foreign ports must be examined. During the year 1911 close to 700,000 cases of merchandise, representing merchandise worth a billion dollars, passed through the Appraisers' Stores, and the goods varied all the way from a toothpick to an automobile, and from a rare tapestry to a dead Chinaman's queue. A sample of literally everything under the sun finds its way at one time or another into the Stores, and no matter what its character may be, whether a fifty-karat diamond or a penny doll, it must be gravely considered and its value accurately and scientifically determined, so that the proper custom duty may be levied thereon. To handle this enormous quantity of material engages the attention of 938 men, of whom 134 are examiners. The duties of the examiner are exceedingly difficult. Each man has a certain classification assigned to him, and he must be prepared to determine the wholesale value of any of the various articles that might turn up under that classification. He must be able to tell of just what material or materials the article was made, how much the materials were worth in the market from which they came, and just what was the value of the labor which was expended upon it. Not only that, but he must know the market values of the materials and labor at the time of shipment. This must be determined on his own knowledge and not on the word of the shipper. He cannot depend on anyone else, but must stand on his own statement, which he must be ready to back up with incontestable evidence in case the importer carries an appeal to a higher court. He must be able to detect all the tricks with which unscrupulous manufacturers delude the ignorant public. For instance, in the textiles department the examiner must be able to tell whether a piece of goods contains cotton, linen or silk, and in what proportion. Having determined this, he must know the quality of the material used in making it up. If it is of silk, he must determine whether the silk is artificial or natural. If natural, what kind of silk, and where it came from. If he is in doubt about the matter, he refers a sample to the laboratory, where the fabric is subjected to a chemical test in order to determine accurately what its composition may be. Naturally an examiner acquires before long such an experience as to qualify him as an expert, an experience that it is impossible to obtain anywhere else.

Recently, curiosities, works of art, and antiques, over a hundred years old, have been admitted free of duty. When the tariff was removed on such objects, this country was immediately flooded with all sorts of curios from every known part of the world, and the poor examiner had to determine whether these objects were at least a hundred years old. When we consider that the articles came from the most remote regions, we can readily understand how difficult was the work. Possibly the most interesting work in this connection is that of determining the age of old furniture. Professionals as well as amateur collectors are duped by clever imitation, and frequently it is not until the examiner in the Appraisers' Stores determines the period to which the article belongs that the purchaser discovers that he has been swindled. Usually the examiner can tell at a glance to what period an article belongs. He is not fooled by artificial weathering or by bird-shot fired into the wood in order to give it a worm-eaten appearance, but he is puzzled sometimes when he finds that around a small portion that really is antique, parts of a more recent date have been applied, or modern wood and varnish have been used to restore a wrecked piece of old furniture.

The examiner who has to appraise the work of artists has an exceedingly difficult task. In many cases it is not at all easy to distinguish between spurious and genuine old masters. The work of these examiners is of undeniable value to the country in preventing the importation of counterfeits.

Similar protection against fraud is found in the case of tea. No duty is levied on tea, but all tea must be examined for purity before being admitted into the country. In the tea room of the New York Appraisers' Stores a hundred thousand samples of tea must be tested per year, which represents an import of about

Testing the color and strength of tea.

forty five million pounds. One of the photographs shows the manner of testing. Each cup contains a different sample of tea identified by a number marked on the bottom of the cup, and one of the cups contains a standard sample. Which one it is the examiner does not know, for the identification of this sample also is marked on the bottom of the cup. The examiner then proceeds to arrange the cups according to the color and taste of the tea. After the grading is done the samples are thrown away and the cups turned upside down to show the identifying numbers. All the samples on one side of the standard are passed as good tea, while those on the other side are rejected. To make sure that no error has been made the test is repeated with a second set of samples. In order to detect any pigment used in the tea the leaves are mashed on a piece of white paper, and then the paper is examined with a microscope for faint spots of coloring matter. The tests are very rigid and thorough and the United States may pride itself on having nothing but pure tea to drink.

Perhaps the most tedious work at the Stores is the testing of sugar. The tariff on sugar depends upon the proportion of cane sugar the samples contain. This is determined accurately by means of a polariscope which analyzes the light that passes through samples of the sugar syrup. When a beam of light is passed through a Nicol's prism the transmitted light vibrates only in one plane. When this polarized light passes through the syrup its plane of vibration is distorted to a certain extent depending upon the quality or nature of the syrup and on the length of syrup it must pass through. By comparing this distortion with a certain standard it is possible to tell just what proportion of cane sugar is contained in the syrup. To prepare the samples for the polariscope fixed quantities of sugar must be carefully weighed, dissolved in a measured quantity of water, filtered and decolorized. The work is very wearisome and trying, with no variation to relieve the monotony. In the case of sugar only samples are brought to the Stores, and as a check upon the examiner, two samples out of each barrel are given him. Each sample bears its own number but the examiners have no means of determining which two came out of the same barrel. Nevertheless, his work must be so accurate that when like samples are paired again the readings will be practically identical.

The laboratories of the Stores are also kept busy with quantitative analyses of various chemical products, particularly in the search for alcohols in medicines, etc. There is also a section devoted to metallurgical analyses.

Obviously it would be impossible to examine every article imported into the country, and so it is the practice to bring at least ten per cent of a shipment to the

Analyzing drugs and medicines for acids, alkalies, oils, etc.

Smuggler's vest, thirty six pockets for watches and jewelry

How the smuggler conceals dutiable goods in books.

Examining cases of drygoods.

Stores. If the shipment consists of but one or two cases of goods at least one case must be examined. The cases that go to the Stores are picked out at random by the examiner. He compares the contents of the case with the invoice and then investigates one of the articles under the invoice minutely in order to determine its quality. If this tallies with the specifications the case is passed. In certain classes of goods, however, the entire shipment must be minutely scrutinized and appraised. In the case of leaf tobacco for instance every package must be opened in order to determine whether the leaves are good enough to be used for wrappers which must carry a duty of one dollar and eighty five cents per pound, or whether they are fit only for fillers, which pay thirty five cents duty. Certain classes of tobacco which are obviously inferior do not come in for such careful examination but in the case of Cuban tobaccos, a hundred per cent must be brought to the Stores. In the appraising of cigars, a very careful count and estimate of weight and value must be obtained, for not only must the tariff be collected but the boxes or bundles must pay a tobacco tax.

We cannot go into all the details of the work at the Appraisers' Stores but we have mentioned enough to show that it is of a most exacting nature. We must also pay a tribute to the high character of the men employed in this work. It is hard to understand how the Government can afford to hire so many experts. As a matter of fact the salaries are not at all proportionate to the experience and quality of work. Frequently an examiner steps out of the Stores into a position with some manufacturer at a salary many times greater than that he has been receiving from the Government. However as a rule the men are content to stay in the Appraisers' Stores because they become devoted to the work and find it full of never-ending interest.

Artificial Marble

THE following are directions for making artificial marble. 1. Burnt gypsum is saturated with a solution of lime in alum water, burnt again, ground finely or rather pulverized, adding 1/12 by weight of the gypsum of alum, and cast in the mold. These harden very slowly, but attain the hardness and transparency of marble. Different pigments may be added to obtain different colored marbles. 2. Pieces of burnt gypsum the size of a fist are put for 1 hours in a 12 per cent solution of alum in water of a temperature of 85 to 104 deg. Fahr., burnt again, pulverized, adding 1/10 powdered alum and lastly worked into molds with water containing 1/16 sal ammoniac for each part of gypsum. Castings made of this combination possess great hardness and brilliancy and it may, therefore, be used for fine statues.—*Neueste Erfindungen und Erfahrungen.*

Power from Kerosene

A System Whereby Oil, Kerosene, and Distillates are Used in the Ordinary Type of Gas Engine

By L. W. Ellis and W. R. Dray

THE intelligent public has been slow to adopt the oil engine. It has been educated by use to internal combustion engines which make an explosive gas out of cold gasoline. Through its familiarity with the automobile it has come to demand an oil engine that follows established gas engine practice. Probably the greatest single factor in such distinction as John A. Secor has earned is his early formulation of the *doctrine* that the oil engine need not and must not vary in principle from the gas engine. Second only to that, however, ranks his discovery of the *means* for using oil without sacrificing a single desirable feature of the best gas engines. His work, which is just beginning to have world-wide recognition, offers an answer to the general demand. The following article, abstracted from a longer article appearing in the February 15 issue of the SCIENTIFIC AMERICAN SUPPLEMENT, explains the principle of the invention.

The Secor patents do not apply to engines which differ from the familiar gas engine type, such as the Diesel and the vaporizing type, nor to the type using the hit-and-miss governor. They are applicable to the throttle-governed engine only.

Stated concisely, the Secor system covers (1) an automatic variation in the quantity of fuel mixture in accordance with the slightest variation in speed and load; (2) a degree of compression dependent upon the quantity of the mixture inhaled; (3) a correct proportioning of the mixture under all conditions, involving relatively weaker mixtures for the higher compressions and increasingly stronger mixtures for the lower compressions; (4) a temperature of combustion exactly adapted to the quality of fuel used and the compression; (5) automatic control of the internal temperature through the admission of water as a part of the fuel mixture; (6) thorough and uniform mixture of the fuel, water and air charge by mechanical means and without the application of additional heat; (7) automatic variation in the time of firing in response to variations in the speed and power; (8) means for changing the limits of relative speed within which all factors are simultaneously controlled; (9) and means for starting on a limited supply of volatile fuel, all of which factors are vital to the control of internal heat, the transformation of heat into power and power production. These features are now embodied in commercially successful engines which have been adapted to a great variety of stationary and traction work.

One great factor in the success of the system is that through the mechanism of the Higgins carbureter the proportions of fuel, air and water are automatically varied in relation to each other as the compression changes. By this means the conditions within the cylinder, whether the engine is run at heavy load or light, are constant so far as they affect the completeness of combustion. Complete combustion eliminates the deposit of carbon, which has been regarded as an insurmountable objection to the use of heavy fuels, and the unified automatic control results in the securing of splendid regulation.

Crank shaft, cam shaft, governor, magneto, carbureter valves and piston act as a positively controlled unit in engines equipped with the Secor system, hence no one mechanical factor deserves to be set apart from the others in importance. However, the Higgins carbureter, which makes possible the application of the Secor system, is of sufficient novelty to warrant special attention. Fig. 1 shows the top view of a two-cylinder tractor motor equipped with the Secor-Higgins system. The cam shaft is gear driven and in turn drives both governor and magneto through bevel gears. The fly ball governor, through a first class lever and a link coupling, operates a sliding brass plate which is clearly shown in Fig. 3. The carbureter sits above the cylinders, with the short inlet manifold presenting little opportunity for the mixture to stratify before it is

Fig. 1.—Top view of two-cylinder motor equipped with the Secor-Higgins system

Fig. 2.—Higgins carbureter, showing air intake and manifold

completely vaporized. It contains constant level chambers for kerosene and water, an overflow being provided for each. It has also, for starting purposes, a chamber for gasoline which is filled by hand pump. This chamber, which holds about a pint, is connected by a siphon with the mixing chamber. Turning the engine over creates suction enough to draw upon the contents of this chamber, but a vent is provided so that if a start is not made immediately the siphon will not continue to act and drain the chamber.

Fig. 3 shows the position of the valve plate at light load. Two air inlets are then open, providing a large ratio of admission to outlet area and thus greatly reducing the relative vacuum in the mixing chamber. As the load increases, the governor throws the sliding valve forward, increasing the area of the outlet to the cylinders, increasing the air inlet in the middle, and decreasing or entirely closing the air opening at the right. Thus the ratio of admission to outlet area decreases, the relative vacuum becomes greater, and more fuel in quantity, though not in proportion, is picked up by the incoming air and carried to the cylinder.

A sectional view from the side (Fig. 4) shows the arrangement of the kerosene and water needle valves, the overflow, etc. It will be noted that the water level is lower than the kerosene level. The suction, therefore, is not great enough, until the engine reaches about half load, to lift the water to the point (H2) where it can flow down the tube surrounding the needle valve. From half to full load the ratio of water to fuel increases rapidly until the amounts of fuel and water used are practically equal.

The carbureter is so designed that the fuel needle valve A should be adjusted at the full load position when the plate is farthest to the right. This order of procedure is important, since at this position the adjustable plate has no effect upon the area of the air inlet openings. The adjustment of the air should be made at the no-load position, and after once made need never be changed unless the engine enters a very different altitude. This adjustable plate allows each carbureter to be adjusted to the engine it is to serve, hence the slight variations in manufacturing are fully taken care of. The sliding valve is the only moving part in the carbureter, and that is positively controlled. There are no springs, floats or check valves. Wear cannot affect the size of the air openings which control the relative vacuum in the mixing chamber, therefore the accuracy of the carbureter will never be interfered with by any ordinary cause.

Ignition is necessarily electric, and in large engines where the speed variation is great, means have been developed for automatically advancing the spark as the speed increases. On ordinary engines, however, only such manual adjustments are needed or provided as will take care of the starting and normal speeds.

One of the most noted gas engine builders in the country has adapted this system to a line of stationary kerosene and distillate engines which will eventually range in size from 50 to 170 horse-power. His factory tests show an efficiency of over 15 brake horsepower hours per gallon of kerosene on 50 horse-power single-cylinder engines at all loads from about one-third to shortly below the maximum. The manufacturer's literature places a guarantee of within 2 per cent on speed regulation. One other large licensee making stationary engines in sizes from 1 to 15 horse-power is achieving considerable success through a series of electric lighting and power outfits suitable for the country home or small business. The generators are direct connected, yet give steadier power than the average public service in the smaller towns. The U. S. Government is using a number of engines fitted with this system to drive air compressors for foghorns in life-saving stations on the Great Lakes.

A six-cylinder marine engine using the Secor-Higgins

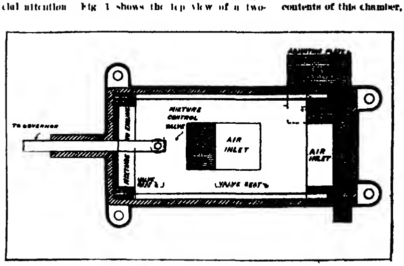

Fig. 3.—Position of sliding valve at light load.

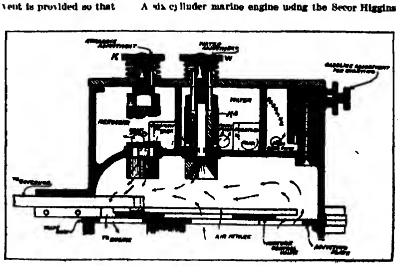

Fig. 4.—Longitudinal section of carbureter.

system develops a brake horse-power hour from 0.9 pint of kerosene. A large number of Secor engines are being used by the Japanese government for operating electric lighting and wireless telegraph stations, and these engines have been adapted to a great variety of uses in this country, where safety and close speed regulation are essentials. Naturally, insurance rates are much lower where a non volatile fuel is used.

The widest use of this system however, has been made in connection with farm tractors. One factory built more than 50 tractors a week as an average for the year 1912. These engines are meeting with universal success, operating on the kerosene and distillates of the United States, on gasoline in South America, and on the lighter grades of crude oil found in the United States and Southern Russia. A two-cylinder tractor, 10-inch bore by 12-inch stroke, running at 375 revolutions per minute, recently developed in an official contest at Winnipeg, Manitoba, 51 brake horse-power in an economy test with a consumption of 0.71 pound of fuel per horse-power hour, and 76.5 horse-power in a maximum test on 0.85 pound of fuel. This is a grade of fuel which sells at 5½ to 7 cents in barrel lots in country towns throughout the Central States, and weighs nearly 7 pounds to the United States gallon.

In the Winnipeg Motor Contest of 1911 a single-cylinder engine of the same type averaged 0.85 of a pint of fuel per brake horse-power hour on kerosene and 0.93 of a pint per brake horse-power hour on gasoline. The kerosene contained 16 to 20 per cent more heat units than gasoline, hence the engine running on kerosene, while a trifle more economical as regards volume of fuel used, was a trifle less efficient thermally. In the last three such competitions, the fuel cost of the tractors operated under these patents has been consistently lowered and has remained at or near the lowest point recorded, while the speed regulation has been scored perfect in nearly every instance. The recent winning of a gold medal and sweepstakes over more than twenty other tractors, including four steam and fourteen gasoline, indicates that the desirable oil burning feature has been achieved without sacrificing any points of excellence. These tractors are being used by ordinary farm hands in every condition of climate and altitude without further adjustment than is provided for in the simple carburetor.

Military Automobile Gun

By the Paris Correspondent of the Scientific American

EVER since the employment of aeroplanes and airships has become one of the recognized elements of modern warfare, attention has been called to the question of cannon for firing upon objects of this kind, and naturally a combination of an automobile with a suitable gun for use in firing at high elevation is sought for. In France where military aeroplane questions are actively taken up at present, designers have been working upon an automobile cannon of this sort, and we here present the most recent and successful type which comes from the De Dion automobile works, the construction having been carried out according to plans furnished by Capt. Houberdon and other army officers belonging to the engineering corps. The automobile is made as light as may be compatible with the load which it is designed to carry, as the car is required to run at a good speed, and to carry this out a good sized 4-cylinder motor is used. On the rear end of the chassis is mounted the cannon with all the proper devices for the firing at a high angle. A turntable base which can be rapidly rotated so as to secure a rapid aiming of the gun is here employed, and another device allows the gun to turn upon its trunnions, the height being regulated by a toothed sector and gearing operated by a hand wheel. All the movements are rapidly carried out, as is required for directing the gun upon objects in the air. When running on the road and out of use, the gun is let down so as to come into the horizontal position, and lies close to the base. During the firing, it can take all inclinations up to 70 degrees, and in this way it fires almost vertically, as our engraving shows. The new automobile gun is meeting with favor in the army, and it has already shown a very good performance in the military manœuvres.

The automobile gun on the road and out of use, comes into horizontal position and lies close to the base.

The automobile gun during firing can take all inclinations up to 70 degrees.

Recent Improvements in the Storage Battery

THERE are about fourteen hundred patents in the storage battery art, as granted by the United States Patent Office. A still larger number is found in the foreign patents. The casual observer might assume

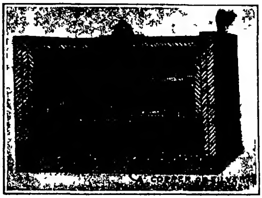

Fig. 1.—Morrison's zinc lead-dioxide cell, showing screens A of copper wire

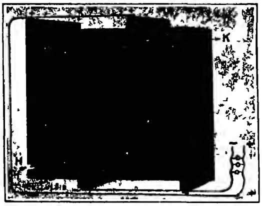

Fig. 2.—Structure of cell used in Basset's electrical battery

from this that there was nothing left to be desired in the battery or that there was no room for further large improvements. On the contrary the perfect storage cell has yet to be discovered. However the present day form of cell is steadily although not spectacularly approaching perfection limited, of course, by certain inherent qualities that cannot be overcome.

The Lead Storage Cell. In the lead storage cell alternate plates of spongy lead and lead dioxide separated by insulators, serve respectively as negative and positive pole electrodes in an electrolyte of sulphuric acid. Upon discharge the lead is oxidized and the dioxide reduced, the resulting products uniting with the acid to form lead sulphate. Upon charging, the reverse reactions occur. Due to these molecular changes the active materials expand and contract. Herein lies the main difficulty in making a battery that will stand up under the stress of usage. The oxides being poor electrical conductors and loosely adherent, a metallic support is essential. The vast majority of patents deal with the structures of such supports. Either a lead oxide paste is applied upon a metallic grid or is held in a perforated container according to the Faure method, or the active material is electrolytically formed *in situ* upon a plate generally comprising thin closely spaced leaves of lead by the Planté process of alternately oxidizing and reducing the plate.

Expanders. Active material where exposed on the exterior of a plate tends to flake off or disintegrate. Of the various expedients to obviate these difficulties, the use of a so-called expander is most common. That is, the active material is impregnated with a finely divided inert insoluble substance, often an electrical conductor. For example, Rodman soaks the dried plate in barium nitrate solution and then dips it in sulphuric acid, thus precipitating insoluble barium sulphate within the pores of the electrode. He also subjects a plate of barium-lead alloy to anodic oxidation in sulphuric and nitric acid, thereby forming lead dioxide and setting free the barium, the latter being then transformed to a sulphate. Ford soaks his plate in a tannin solution containing deflocculated graphite in suspension. Morrison uses oxygen compounds of chromium, tantalum, niobium or tungsten. For example he electrolyzes the ordinary lead dioxide plate as an anode in a sodium tungstate solution, thereby forming a tungsten oxygen compound within the pores of the electrode. Morrison also describes the use of such agents as nitro-celluloses, especially celluloid, or rubber vulcanized in the plate.

Initially Formed Active Material. Salom works on the problem from another viewpoint. He first electrolytically forms or, as it were, charges the spongy lead or lead dioxide, so that it is initially fully expanded, and then applies it to the grid under hydraulic pressure. The spongy lead is bonded by allowing water to evaporate from the powdered lead crystals, thus oxidizing it superficially throughout.

Quick Discharge. An essential for a quick discharge is that the pores in the active material be so large that the acid does not become impoverished at the working surfaces. This has been accomplished by mixing the lead oxide paste with various compounds which are dissolved when the plate is formed, such as sugar, salt, various silicates, carbonates, etc., or powdered metals, such as zinc dust. Marino specifies an agglutinant of glycerine, soluble starch and water glass. Others make up a Planté plate of a lead alloy, such as lead-zinc, and afterward chemically or electrochemically dissolve the zinc or other alloying metal.

Hannover in Denmark casts a plate from a mixture of a metal and an alloy, e. g., of lead and antimony, applies heat until the eutectic alloy becomes fluid while the remainder is solid, and then squeezes out the fluid particles leaving a spongy plate. He then galvanically precipitates metal of a higher melting point within the pores, heats and melts out the original material.

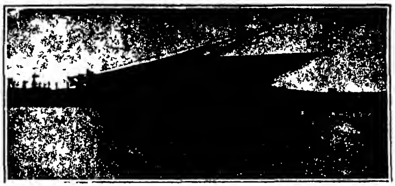
Tate accomplishes the same end in a bifunctional electrode made up of interleaved strips, alternately positive and negative and suitably separated by porous earthenware plates, which carry a supply of acid. Each strip is about one-half inch wide and the active material is but one thirty-second inch deep, thus exposing substantially the whole mass to the electrolyte.

The Iron Nickel Cell. The iron nickel

(Concluded on page 264.)

Ice-boating

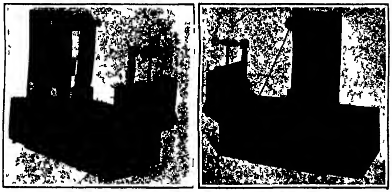
A FEW weeks ago we described the exhilarating sport of motor ice-boating, and showed some of the more substantial types of motor-driven sleds. One might be tempted to think that the motor ice-boat would eventually render the wind driven iceboat obsolete. Such, however is hardly likely to be the case when we consider the rare sport that can be obtained with the wind propelled vehicle. The accompanying photograph shows an exciting moment in an ice-boat race. The ice boat is lifting to an alarming angle and it seems as if it must surely topple over but it will right itself and continue on its course. Surely a sport affording such exciting moments is not liable to die, for ice-boating is purely sport, and there is no utilitarian reason for introducing motors as has been the case in sailboats. The only reason for the motor ice boat is that it affords a different kind of sport. The two types of ice vehicles will surely be continued and developed side by side.



An ice boat "lifting" to an alarming angle

The Micro-monophone

THE micro-monophone is a tuning fork kept in permanent vibration by means of a microphone contact. This is an improvement over the familiar tuning fork interrupters for the reason that its sound is much clearer while the current curve approaches much more closely to a sinusoidal form. Two views of the apparatus are shown herewith. The tuning fork is mounted upon a resonance box. The prongs of the fork are situated in the field of an electro-magnet on which is superposed the field of a permanent magnet. The coils of the electro-magnet are arranged in series with a microphone mounted at the closed end of the resonance box. The support for the microphone is such that it may be moved to bring the lower carbon electrode into contact with the resonance box. When current from a battery is passed through the microphone and the electro-magnet and the tuning fork is set vibrating by means of one or two slight knocks, vibrations will be transmitted through the resonance box to the microphone producing variations in the magnetic field of the electro-magnet which in turn acts upon the tuning fork and keeps it vibrating. Thus we have a complete cycle of operation, the tuning fork keeping the microphone in operation and the latter by means of the magnet keeping the tuning fork vibrating. The tuning fork will then vibrate as long as the battery current is complete or unbroken. By reducing the current intensity the purity of the sound is increased.



Apparatus for keeping a tuning fork in constant vibration.

Acorns and Their Uses

VERY little attention has been given in this country to the utilization of acorns. It is well known that they are used as food for cattle, horses, swine turkeys, and those of several species of white oaks also form the food of man.

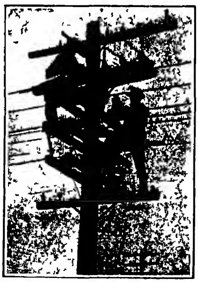
The acorns of white oaks are mostly large and the trees in general produce fruit very abundantly. The Indians in California always gathered the acorns of the California live oak (*Quercus agrifolia*) and years of great scarcity often caused much misery. Even the early white settlers of California relied on the crop of acorns as a part of their food supply. The acorns were gathered by the squaws, who preserved them by putting them in wicker baskets which were generally stored in hollow oak trees or in caches as shown in the illustration. They were prepared for eating by grinding and boiling them with water into a thick paste which was baked into bread. The oven consisted of a hole in the ground about 18 inches each way. Red hot stones were placed in the bottom of it and a little dry sand or loam placed over them. Next a layer of dry leaves was spread over this and the dough or paste poured into the hole until it was two or three inches deep. A layer of leaves, more sand, red hot stones, and finally earth was placed on top. At the end of 5 or 6 hours the stones had cooled and the bread, which was an irregular mass nearly black in color, was taken out.

In parts of the South acorns of the cow oak (*Quercus michauxii*) have been used when roasted as a coffee substitute, and there are a good many other uses to which they might be put. Alcohol can be extracted from them, as from all starchy substances. Starch is at present made principally from rice, corn, and potatoes, but if the starch from acorns is sufficiently refined it may be employed as an article of diet as well as for laundry purposes. Acorns contain much sugar and gum, and it is probable that these substances can be profitably separated and successfully used for domestic purposes. Even the residue could be sold very profitably for fattening hogs.

Transporting a bridge girder in Southern India.

Engineering in Southern India

AT first sight there appears to be nothing very remarkable in the accompanying photograph which shows the floating into position of a large girder. The girder is a hundred and fifty feet long and it is supported in the well known manner upon two floats to permit of transporting it down the river. The weight of the girder is 200 tons, certainly not remarkably heavy. But closer inspection of the photograph shows a small boat on the river with a lateen sail, and in the foreground a dugout canoe which gives us the hint at once, that the girder is being transported on some Oriental stream. It seems rather incongruous, does this introduction of a bit of western engineering in the picturesque Oriental stream. The girder is being floated down the Netravati River at Mangalore Southern India over which waterway a bridge is being built. Although the transporting and placing on its piers of such a girder is a simple matter in our land it is no inconsiderable feat where ignorant native workers must be relied upon.



Protected by shields in a network of high-tension wires.

Standing on the shields while fixing an arc lamp.

Rubber Shields for Linemen

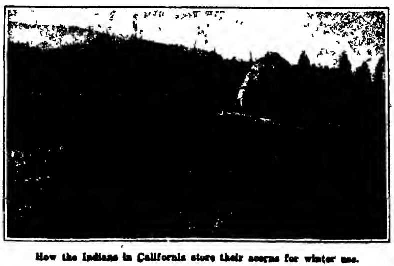
OF the millions of people employed daily about exceedingly dangerous tasks, few are subjected to greater danger than the linemen employed by the thousands upon thousands by electric lighting and power companies. These men daily place themselves in the most hazardous positions among high tension wires. For the protection of this class of employees a rubber shield has been invented.

The shield has the form of a rubber trough. It is used in all possible positions where the body of the operator may be exposed and is also used as a means of protection in trimming arc lamps and repairing broken wires from the ground. In the latter case if the weather is dry the shield is simply stretched upon the ground for the repairman to stand upon, but in case of wet weather when this insulation is not sufficient the shield is closed at the flaps.

The appliance is manufactured of pure Para rubber, three layers of the rubber being used to two layers of canvas, the latter alternating with the rubber sheets. The second layer of canvas used is laid crosswise to the first layer, and in this way adds greater strength to the shield. The thickness of the rubber varies from 3/8 inch in locations where it is liable to be subjected to pressure to 3/16 inch along the closing flaps. The contrivance is fastened to the wire by two hard rubber rings. These are slotted with an aperture sufficiently large for the wire to enter and then clamped by this means firmly to the wires from which the lineman must be protected.

Each shield is subjected to a test of 30,000 volts submerged, but it is recommended that the protector be used only with voltages not exceeding 10,000.

It will also be noticed that this new life-saver fits over the insulators, and in fastening it to the wire the lineman grips the rubber handles attached to the outside ends of the shield in such a manner that it is between his hands and the wire.



How the Indians in California store their acorns for winter use.

Inventions New and Interesting

Simple Patent Law, Patent Office News: Notes on Trademarks

A New Gear Engine

TWO small spur gears cutting through a steam chamber at their intermeshing point—this is practically all there is to an engine, which has recently been tested at the laboratory of Columbia University, at the power house of the New York Central Railroad, and at the Chicago and Northwestern power house, where it developed thirty five horse-power with better economy than the average multi stage turbine or piston engine of equal power

The construction of the engine is shown in the accompanying drawing, in which the two gears *A* are mounted in a suitable casing *B* At their intermeshing point there is a centerpiece *C* containing two steam chambers, for this is a reversing engine The dotted lines *D* and *D'* outline the chambers, and they communicate with the pipes *E* and *E'*, respectively When steam is admitted through the pipe *E*, it fills the chamber *D* and can escape therefrom only by propelling the teeth of the gear wheels in the direction of the arrows. The escaping steam fills the casing *B*, and most of it escapes through the exhaust *F* Some of the steam is carried by the teeth into the chamber *D'*, and escapes through the pipe *E'* which is connected with the exhaust When it is desired to reverse the engine the pipe *E* is connected with the exhaust and steam is admitted to chamber *D'* through pipe *F'* Such is the construction of the single stage type of engine Very evidently the parts may be duplicated to produce a multi stage gear engine

The following is a report on the engine tested at Columbia University Mechanical Laboratory and the New York Central Power Station

"The results show a very good water rate for this size of unit The engine has the following salient points of design, Speed may be varied over a wide range. Weight per horse-power and floor space per horse power are very low No foundation is required for this size unit, the machine tested was operated without vibration under load up to 4,000 revolutions per minute standing on a wooden bench. There are of course, no dead centers and no reciprocating parts. The external gears establish the running clearance of the working gears, so that there is no contact and no lubrication in the engine required It has a high starting torque, as the full steam pressure can be utilized at the outset. The engine is symmetrical with respect to steam and exhaust, so that it can be reversed without difficulty and operates equally well in either direction. The engine is entirely inclosed, and slugs of water have no effect except a temporary slowing down As the engine can be equipped with two pulleys revolving in opposite directions, belts can be operated if necessary on very short centers, as one pulley can act as an idler in securing additional wrap on the other pulley It obtains its good water rate by eliminating most of the other losses which occur in small engines and turbines, such as cylinder condensation and leakage in a reciprocating engine, and windage and steam friction in turbines."

This engine easily delivered 50 horse-power on the brake and the above figures were estimated from that basis.

Various tests have been made in the past on the single-stage unit to determine the increased economy of the multi-stage gear engine. The results of these tests have brought to light an entirely new method of expanding steam, heretofore unknown to authorities on thermodynamics. The expansive power is obtained in this new cycle while the steam is working at a continuous flow against a series of pistons, having what is termed an infinite receiver between them, which consists of merely steam passages between successive and closely adjacent stages the number of stages determining the amount of expansion obtainable. The following is quoted from a report by Prof Parr based upon tests made by Prof Pigott both of Columbia University

Machines for Printing Railroad Tickets

IN a large railroad system the cost of supplying storing and issuing tickets to passengers is no small item In the system generally followed in this country each station agent is required to keep on hand a stock of complete tickets for each principal station on the road and blank tickets for the less important ones in which the name of the destination is written or printed with a rubber stamp This latter class of tickets is always a source of trouble, as that they are subject to forgery and the liability to error in accounting Furthermore, cumbersome ticket cases are required to hold these tickets and in large stations such cases take up much valuable space

In view of the foregoing facts it would appear that a comparatively simple and practicable machine by which it would be possible for the ticket agent to print each ticket as it is called for would receive careful consideration by the railroad companies Many ingenious machines have been invented for doing this work Practically all of them have a fixed plate for printing the body of the ticket such as the name of the road the conditions under which the ticket is sold etc, and movable or removable type plates for the place of destination and date They also are so arranged that at least the destination of each ticket printed is also printed on an auditing strip which is of great assistance to the agent in auditing his accounts, and may be turned in with his reports.

In Fig 1 is shown the first complete machine of this kind patented in this country in 1873. A roll of paper in ribbon form having printed thereon the main body of the tickets is placed in the lower cylindrical part *a* of the machine The end of this ribbon passes up over a feed roller in the upper cylindrical part *b* and thence out over the platen at the top A curved arm *c* is pivoted at the back of the machine and at its front are recesses for removably holding the type plates *d* for the destination and the date At each complete revolution of the crank shaft the paper strip is fed forward the space of one ticket and by means of eccentrics an ink ing roll *f* is passed over the type plates and the arm is brought down on the platen thus completing the ticket The ticket thus printed is then cut off The auditing strip lies alongside the ticket strip and is fed forward at a slower rate and the identifying matter is printed thereon at the same time the ticket is printed

The next view (Fig 2) shows one of the most recent forms of this type of machine In the upper part of the casing is a horizontal shaft turned by a crank and carrying a mutilated bevel

(Concluded on page 260)

Fig 2.—One of the most recent forms of printing machines, in which all tickets are numbered with one serial number Fig 3.—In this machine the tickets to each station are printed with their own serial number Fig 4 shows an improved machine with the cash register feature.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

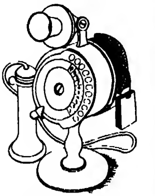
Pertaining to Aviation.

AEROPLANE.—J. ANDERSON, West Mount Vernon, Maine. This invention provides carrying planes; provides a carrying structure manually controlled to effect a proper means for facilitating the banking of the machine when turning a curve or to regain its equilibrium; provides a car to protect the aviator and motor with the least retardation of the flight; provides an inclosed casing for the motor employed in conjunction with the aeroplane having an exhaust duct opening at the rear to convey the sound of the exhaust away from the aviator; and provides a car body shaped to the wave line of flight to avoid the suction at the rear of a fast moving body.

Electrical Devices.

HIGH VOLTAGE STRAIN INSULATOR.—L. STEINBERGER, Brooklyn, N. Y. Mr. Steinberger's invention relates to strain insulators for high voltage electric conductors to be used in various relations and for various purposes such as power transmission, and for guy wires or cables employed as stays for towers or for poles, masts and other supports used in wireless telegraphy and telephony, as well as in ordinary commercial work.

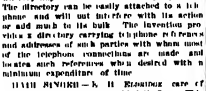
TELEPHONE DIRECTORY.—J. SOSTHEIM, Eu. 1440 Emerson St., Lincoln, Neb. This invention relates to telephone directories and more particularly to a device which comprises a plurality of circular members carrying reference characters and provided with means



TELEPHONE DIRECTORY

whereby any desired reference is rapidly found. The directory can be easily attached to a telephone and will not interfere with its action or add much to its bulk. The invention provides a directory carrying telephone references and addresses of such parties with whom most of the telephone connections are made and locates such references when desired with a minimum expenditure of time.

HAIR SINGER.—E. H. ELDRIDGE, care of Peoples Light Co., Corpus Christi, Tex. This singer is adapted to ease and rapidity of operation and is characterized by a pocket adapted to receive the smoke resulting from singeing hair, thereby doing away with odors, there being a reduction of pressure within the pocket and maintained by any suitable means. The singer has a heating element adapted to en-



HAIR SINGER.

gage the hair as it is lifted or raised by means of a comb or similar article whereby the ends thereof may be singed, the burned material and smoke resulting therefrom being carried into the pocket in the device and conducted away.

Of Interest to Farmers.

DRAFT ATTACHMENT FOR BINDERS.—H. J. DEAGAN, Orlando, Okla. This invention provides an attachment supported on carrying wheels and provided with means for attachment to the body of the binder in the cutting position of the same, and with means for securing the platform of the binder upon the attachment when transporting the binder from place to place.

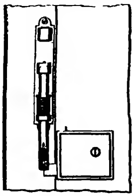
CANE PLOW.—W. L. BOATRIGHT, Glendale, and A. J. McNEILY, of Columbia, Tenn. Address J. C. Yorkes, Columbia, Tenn. The object in this instance is to provide means for supporting a gang of plows in such manner that the plows will be yieldingly held spaced apart laterally and wherein the plows may yield upwardly and may be set to cut at varying depths, loosening but not turning the soil.

WILD OATS SEPARATOR.—A. HOLLAND, Nome, N. D. This inventor provides a device having a few parts and consequently not liable to get out of order, which will quickly and effectively separate the wild oats from the cultivated oats, delivering the former at one end of the device and the latter at the other end.

Of General Interest.

TOOTHACHE REMEDY.—D. FRIEDSOHN, 1822 Madison Ave., New York, N. Y. By use of the paste of this invention in an affected tooth quick relief of pain is had, and at the same time the paste on hardening forms a temporary filling, thus protecting the nerve and pulp against air, solid food and hot and cold liquids.

ALARM.—E. C. RICKER, Scranton, Pa. The object here is to provide an alarm device adapted to be used on either side of a door casing with doors opening in either direction. Further to provide in a certain structure an alarm device which will give warning whenever an attempt is made to open a particular door, thereby either frightening away an in-



BURGLAR ALARM

truder or making his capture easy. This thief and burglar alarm gives warning through the explosion of a cartridge or other explosive constructed and arranged to be set or engaged from either side of a door or opening and particularly adapted to engage with the bolt of a rim lock and released by a push or pull from either side of the lock or other suitable connection.

SODA FOUNTAIN ATTACHMENT.—H. A. GRIFFIN, Drawer 8, Rocky Mount, N. C. This invention is an attachment for spigots of soda founts for stirring and mixing the syrup or flavoring extract with carbonated water in drinking glasses, this operation being effected automatically by the flow of the carbonated water when discharged into the glasses, which have been previously supplied with a due quantity of syrup.

AWNING FIXTURE.—E. H. WEAVER, 23 Gregory St., Jersey City, N. J. This inventor provides hanging fixtures for the head bar of awnings which may quickly be installed and removed from service position and provides socket for hanging fixtures adapted to hold the fixtures in a substantially vertical position to avoid the cramping of the fixtures and the rod when in service relation.

HORSESHOE.—H. K. KING, Temple Court, 1 Beekman St., New York, N. Y. The object here is to provide an overshoe to fit on the hoof over the ordinary shoe in order to prevent slipping or sliding on ice or wet pavements, and so constructed that the different parts may be readily attached together and to the hoof of the animal, the overshoe being so arranged that the parts brace one another and readily conform to the configuration of the hoof. This is attained by placing a reinforced pad under the hoof and fastening this pad to the hoof by means of a particular framework and straps.

Hardware and Tools.

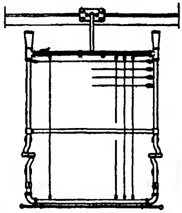
BELT BUCKLE.—L. SANDERS, 621 Broadway, New York, N. Y. It is the design of this inventor to provide a buckle in which the housing and back plate shall have such conformation and relation to each other and such a correlation with the roller that the roller will effectively grip a belt of any thickness ordinarily handled by the trade.

COMBINATION TOOL.—C. A. NORBERRY, P. O. Box 306, Fort Bragg, Cal. This invention comprises a miter square having a pivoted blade with a protractor attachment to indicate the position of the blade, a spirit level and scratch awl, a recess or notch in one edge to adapt the device for use as a center gage and a plurality of means carried by the pivoted blade for marking a mortise on lumber, by the person using the tool.

Household Utilities.

HOLDER FOR BROOMS AND LIKE ARTICLES.—A. L. ROSS, 763 Lexington Ave., New York, N. Y. For the purpose of this invention use is made of a wire bracket adapted to be fastened to a wall or other support, and a wire bail for the passage of the stick of a broom or other article, the bail being mounted to swing on the bracket and being provided with a pin adapted to engage the stick at the rear side thereof.

FOLDING AND REVERSIBLE BED.—D. J. SPINKS, 141 Stone Ave., Tucson, Ariz. This invention has reference generally to beds, the object being to provide a folding and reversible bed frame which is particularly adapted to be permanently mounted between two rooms, for



FOLDING AND REVERSIBLE BED.

instance an inside sleeping room, in such manner that it may be readily and quickly folded to assume an operative position within either room and also movable to an upright or folded position within either room in which it may be in use.

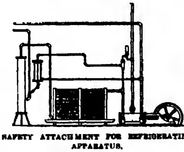
Machines and Mechanical Devices.

SAW TENSIONING AND STRAIGHTENING MACHINE.—T. W. ROACH, Lyman, Wash. This improved machine is especially designed for operating on circular saws although not limited in all its features for use with circular saws. The machine is serviceable also for use in straightening a concaved saw that has been forced over the saw collar.

VALVE.—M. J. WALSH, 124 E. Pine St., Mahanoy City, Pa. This inventor provides a blow off valve so constructed that the main valve and its valve seat may be moved to a position outside of the casing whereby it may be ground or otherwise repaired, and provides an auxiliary valve and valve seat which closes the valve and prevents leakage to the atmosphere at and during the time the main valve and its valve seat are exposed for repairs.

SPRING HAMMER.—J. H. PHILLIPS, care of Dougherty Smith, Phillips Co., Oklahoma, Okla. This invention more particularly relates to a mechanically-actuated hammer. It is an improvement over the hammer in Mr. Phillips' co-pending application serial No. 533,867. An object of the present invention is to provide a hammer which is automatic in its action and which will receive its direct force from a compressible spring.

SAFETY ATTACHMENT FOR COMPRESSION REFRIGERATING APPARATUS.—F. A. SCHNEIDER, 295 E. 162nd St., Bronx, N. Y. This invention relates to refrigerating and ice making systems, and its object is to provide a safety attachment for compression refrigerating apparatus arranged to automatically shut off the ammonia to the expansion coils, and to sound an alarm in case the pressure in



SAFETY ATTACHMENT FOR REFRIGERATING APPARATUS.

the systems exceeds the normal pressure. In order to accomplish the desired result use is made of means for closing a valve controlling the ammonia to the expansion coils, and for sounding an alarm.

Railways and Their Accessories.

AUTOMATIC CAR OILER.—J. T. McREYNOLDS, Lilly, Ill. The object of the invention is to provide an inexpensive automatic car oiler simple in construction and efficient in action inclosed in a car journal box, and the efficiency of which is independent of the direction of rotation of the axle.

OPERATING DEVICE FOR STATION INDICATORS.—W. B. HILL, Hotel Senera, San Francisco, Cal. The object here is to provide a simple and efficient operating device especially adapted for use with the type of indicator shown and described in Mr. Hill's co-pending application No. 566,245. The device is operated by fluid under pressure, and the display mechanism may be operated by trips preferably arranged on the trolley wire at places where announcements are to be made, or by mechanism driven by movement of the car which mechanism will actuate the displaying device at the proper intervals.

RAILWAY CONSTRUCTION.—G. SYMES, care of Coughton & Brecse, Mason City, Iowa. The invention is an improvement in the class of railways in which the running rails rest on arched metal chairs or supports that are in turn secured to transverse metal ties. The invention is embodied in the construction and connection of the chairs or rail supports and the transverse ties connecting them.

NUT OR LOCKING DEVICE FOR SCREWS.—G. LASKOVSKY, 5 Avenue du Bois de Boulogne, Paris, France. This inventor provides a nut or locking device for securing screws and particularly for the screw spikes in railway sleepers. The device offers great resistance to the tearing out of the screw spikes even when the sleepers are made of soft wood.

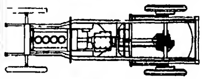
FLANGE OILER.—C. F. HOOVER, 345 Chemical Block, Spokane, Wash. This invention refers to improvements in devices for lubricating flanges of locomotives and other track vehicles. An object is to provide means whereby the flanges of locomotives or other vehicles may be oiled automatically at certain places where such lubrication is most necessary, such as on curves in the track.

Pertaining to Recreation.

GAME.—F. C. CRAW, 4459 Evanston Ave., Apartment N, Chicago, Ill. The intention here is to provide an improvement in games, in which is provided a board representing a baseball field and a series of figures representing the players, and wherein the figures may be manipulated on the board to imitate the movements of actual players in the game of ball.

Pertaining to Vehicles.

AUTOMATIC BRAKING DEVICE FOR AUTOMOBILES.—J. E. FISHER, JR., 84 W. 76th St., New York, N. Y. This invention relates to braking mechanism for automobiles and motor vehicles in general, and it is designed to be automatically thrown into action



AUTOMATIC BRAKING DEVICE FOR AUTOMOBILES.

to prevent racing of the driving wheels of the machine when, owing to the nature of the road, or from any other cause, frictional engagement of one of the driving wheels with the ground is lessened. The engraving shows a top view of an automobile having the braking device in position thereon.

VEHICLE AXLE.—J. E. HENGER, Winterpock, Va. This invention is an improvement in that class of vehicles having detachable

VEHICLE AXLE.

journals or spindles, and particularly in that class in which the axle ends are slotted and the journals or spindles provided with shanks adapted to fit in such slots. The chief objects of the improvement are to avoid weakening the axle by the construction required to affect such engagement.

Designs.

DESIGN FOR A HAMMER.—H. B. WILSON and H. O. GEPHART, care of Van Dorea Mfg. Co., Chicago Heights, Ill. This ornamental design for a hammer represents an implement of excellent proportions, and the effect of the angles in this design contributes to producing a hammer of very fine lines. The same designers have patented another design of a hammer which corresponds with the first, except that the end of the tool is perfectly plain.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

The Industrial Need of Technically Trained Men—I.

Scientific Manufacturing and the Opportunities It Offers

By Waldemar Kaempffert, Managing Editor of the Scientific American

[IT is the intention of the SCIENTIFIC AMERICAN *to publish a series of monthly articles on the professional opportunities that await the technically trained engineer physicist, chemist, bacteriologist and technologist in modern life. Last year, it will be remembered, a series of articles was published written for the most part by well known educators connected with our leading technological institutions. They showed how institutes of technology were endeavoring to meet the requirements of great manufacturing railway and municipal corporations This year's series, written by the heads of great corporations—companies which are capitalized at millions of dollars, which employ thousands of men, and which are scientifically organized and managed—will show how great is the need of trained chemists and engineers As an introduction to the series we publish the following review by our Managing Editor, the purpose of which is to give a glimpse, as it were, of the rich prizes that can be won by the trained technologist* —EDITOR.]

The modern manufacturing corporation, which requires acres of floor space to carry out its processes, which each day converts whole train loads of wheat, leather or iron ore into flour shoes, or steel rails, needs brains more than brawn. So vast are its operations that it pays to save a few cents in the production of a ton of pig iron, to devise a steam shovel which will scoop up five tons of ore at a time with a slightly less consumption of energy than was possible before to analyze chemically the wastes of manufacture and to devise means of utilizing them No manufacturer can afford to ignore the technologist Competition is no longer consigned to the selling market There is a rivalry in improving manufacturing methods as well as in merchandising Millions are annually spent by business men on scientific and engineering investigations that would have been regarded as purely academic twenty years ago but the ultimate commercial value of which is immediately apparent to the broad minded merchant of to-day Even the manufacturer who employs only a dozen men must engage in this intellectual rivalry He cannot always afford to engage permanently a laboratory expert but he must at least obtain the advice of a consulting chemist or engineer if he is not to be utterly crushed.

Despite its utilitarian and commercial character much of the scientific investigation undertaken by the great modern manufacturing corporation has a fascination all its own Indeed, the results achieved often affect not simply one particular industry, but a whole science In the city of Cleveland for example one of our great electrical companies maintains a number of laboratories, the sole purpose of which is to improve our methods of illumination, and to give us a light which is more efficient than anything now produced The studies there conducted involve chemical and physical research of a high order, physiological and psychological studies of the effect of various illuminants on the human eye engineering researches that will measurably bring us nearer to the "cold light," of which illuminating engineers have lately written so much In a word the entire subject of light is studied with a thoroughness never before attempted and with a total disregard of money Who can doubt that research thus conducted will not simply enrich the world with illuminants better and cheaper than anything we have now, but that the whole science of optics will assume a new importance?

Because of the huge capital which it commands, the modern manufacturing company can experiment on a stupendous scale to realize an idea correct in theory The development of the Curtis steam turbine for example involved the expenditure of millions That vast sum was not spent in empirical experimenting, but in practically testing the thermo-dynamic views of engineers whose one task in life was the perfection of the steam turbine Work such as this is comparable with the finest research conducted in any university What is more, it is richly paid for, for your great manufacturing corporation, unlike your great university, is not niggardly in rewarding the trained men to whom the development of its processes is due.

It has been supposed that the all-devouring trust crushes its weaker rival by the sheer weight of its money The truth is that trained minds easily triumph over mere money In twenty-six public hearings recently held in Washington by the House Committee on Patents, to consider the views of inventors and manufacturers on the advisability of introducing compulsory licenses into our patent system, it was abundantly demonstrated that the trained technologist is more than a match for the trained capitalist The patent counsel for the greatest sewing machine manufacturing company in this country testified that were it not for the experimental laboratories conducted by three or four smaller sewing machine manufacturers, the company that he represented would undoubtedly monopolize the market In other words, a handful of highly paid and splendidly trained technical men were able by sheer ingenuity to cope with the dominating company

Before the same Congressional committee Mr Spencer B Miller a well known engineer, drew a vivid picture of the manner in which a modern manufacturing company utilizes trained engineers. Mr Miller has made a life study of conveying machinery To him we owe the system of coaling battleships at sea, which has been adopted by the United States Navy He revealed the manner in which his company had deliberately studied market conditions and devised machinery to meet special needs. Cypress logs, for example had long been hauled out of Louisiana swamps at an enormous cost Mr Miller was engaged to devise the best mechanical system possible for taking out the logs. He did so with such success that not only were cypress logs eventually sold far below their old price but that swamp land which had once brought only \$1 an acre, commanded \$75 per acre. Experts like Mr Miller, trained in technological schools are needed more and more. The American telephone system a marvel of efficiency, is the creation of a dozen engineers whose work is confined entirely to the improvement of telephonic communication They are engaged at princely salaries to meet the needs not only of to-morrow but of the day after to-morrow to devise systems for which there is no immediate use but which will become of paramount importance when a city of two million inhabitants has increased in population by one hundred per cent.

Those who have read the addresses of the recipients of the Perkin medal, awarded for distinguished achievements in chemical engineering, must have been struck with the opportunities that await the trained man in that one field alone. Herman Frasch told how the application of chemical principles enabled him to rid Canadian oils of their sulphur, and thus to make them more generally salable, how he had improved the methods of salt mining and above all, how he had successfully solved the problem of raising to the surface the sulphur buried beneath Louisiana quicksands, after a dozen men before him had failed So, too, James W Gayley, an academically trained metallurgist and a former vice-president of the United States Steel Corporation, showed how, with his dry blast process, he had markedly improved our methods of reducing iron ore.

At the International Congresses of Hygiene, Chemistry and Testing Materials, held last year in this country, paper after paper was delivered bearing ample testi-

many to the achievements of trained men in modern industry, and therefore indirectly proved the opportunities that awaited the technical graduate. Thus, in discussing the production of synthetic rubber by Harries and Hofmann, Prof. Duisberg showed how all the resources, both technical and financial, of a great German chemical company are being used in endeavoring to produce rubber by artificial means so cheaply that the chemical factory can some day compete with the plantation—a work on which dozens of trained chemists have been unremitting ly engaged for years. Prof Bernthsen showed how important has been the aid of the trained chemists employed by the company of which he is the head, in reducing nitrogen from the air, so that the exhaustion of the Chilean nitrate beds, so frequently prophesied, is no longer a cause for alarm. Nearly every one of the papers read before the societies mentioned was prepared by men who are employed by European and American manufacturing companies. They revealed how refined are the scientific methods which are now necessary in carrying out manufacturing processes on a large scale, how hopeless it would be to attain the same result with the aid of men who have not had the benefit of listening to a great teacher in a great technical institution and how increasingly necessary is the employment of the technical graduate in modern industry

Recent Improvements in the Storage Battery

(Concluded from page 247.)

cell consists of electrodes of spongy iron and nickel hydroxide in a caustic soda solution. The caustic soda serves merely as a carrier of ionic oxygen and hydrogen and does not become exhausted, so that impoverishment of the electrolyte is not a serious difficulty, as in the lead cell

In order to increase the conductivity of the active masses, Edison impregnates both the iron and the nickel electrodes with a bismuth compound The bismuth reduces to the metallic state in the iron electrode upon charging, thus forming conducting veins throughout the mass. Estelle, in Sweden prefers to add cadmium Aschenbach uses boron Others have shown the application of the Planté process of electro-chemical formation to these electrodes.

Zinc Lead-dioxide Cell: The substitution of zinc for the spongy lead plate commends itself because of the material increase in voltage. A difficulty lies, however, in the fact that zinc dissolves during discharge, and in being electroplated out upon charge, it tends to deposit in a porous, loosely adherent mass, and so become dislodged from its support This condition necessitates the use of horizontal electrodes, the zinc preferably being in the bottom of the cell Numerous modifications of this type are found, in which zinc is combined with various elements.

Morrison shows a number of screens of woven copper wire *A* (Fig. 1), these screens being silver or copper plated and amalgamated by dipping with mercury Zinc is electroplated upon this support during charge. The upper electrode *B*, separated from the lower one by an insulating plate *E*, may be made of aluminium, copper, silver or nickel. Morrison so proportions the relative quantities of the zinc and the caustic soda electrolyte that only a part of the zinc dissolves, the rest remaining on the support and merely oxidizing. Morrison also has found that the zinc is held insoluble by the addition of cadmium

Other Battery Combinations Perry has a positive pole electrode of nickel and silver oxides, an electrolyte of potassium zincate and a negative pole plate of zinc. A combination of zinc, chromium and mercury for the negative pole plate and mercury and silver oxides for the positive is used by Morrison. He prefers an electrolyte of caustic potash containing chromium hydroxide or a chromate.

Regeneration: The lead sulphate formed in the normal discharge of the lead cell

should remain scattered throughout the plate in a finely divided condition, so that upon charging, it may be readily transformed to the oxide or the spongy lead. When the sulphate collects in large white patches, which are non-conducting, and so remain unchanged during the battery action, the cell is said to be sulphated. A regeneration of such sulphated batteries is accomplished by Luckow, Friedrich and others in the following general manner. The cells are emptied, washed out and filled with water. The acid clinging to the plates furnishes sufficient conductivity. A current is passed through the plates in a direction opposite to that of charging for 4 to 8 days, with a current density of 20 to 50 amperes per square decimeter, until the plates are completely reversed, the oxide to spongy lead and *vice versa*. The current is then passed in the opposite direction for 3 to 6 days more, and finally the plates are charged in the regular acid bath. The electrolyte for this regeneration may be a one per cent solution of potassium or sodium sulphate, carbonate, borate or hydroxide. The last three compounds serve to neutralize the sulphuric acid set free during the process, thus keeping down the apparently objectionable acidity.

Preserving the Electrodes. It is known that lead, zinc and iron electrodes tend to oxidize on drying. This brings a mechanical difficulty into the shipment or care during long continued disuse of such plates. A German patent to Heym states that if the negative pole plate is washed and then dried in a vacuum or in gases that do not attack the metal, it does not oxidize upon being brought into the air.

Separators. The ordinary perforated plates of rubber or celluloid often allow the lead to "grow" through the perforations and bridge the electrical gap. It, therefore has been found necessary, in many instances, to use a porous diaphragm also. Wood is found to be most suitable, but certain impurities, such as acetic acid, resins, vasculose, etc., which are injurious to the lead active materials must be removed. This may be done by treatment with an ammoniacal solution of copper oxide, by oxidation by means of hydrogen peroxide, nitric acid, hypochlorites, etc., or by solution in alkali and alcohol. Marino treats with steam under pressure and then with hydrogen peroxide. Dodge soaks the wood successively in sulphuric acid and potassium hydrate. DeMartis treats a woven fabric in a similar manner, so as to have left only the pure cellulose.

Circulating Electrolyte. Because of the well known limitations of the regulation storage battery, two other theories are being made the basis of experiments: that of circulating the electrolyte around or through the electrode and that of generating current from various exothermic chemical reactions, using inert electrodes. By the first method, the reaction products are forced from the pores of the electrode, either continuously or intermittently. For example, Hite circulates the electrolyte along the face of the plate and through the mass of a suitable depolarizing oxide, made porous by being mixed with asbestos or cement. Benko forces an electrolyte carrying oxygen or chlorine in solution through the pores of a carbon cathode, zinc being the anode. In the lead storage cell, Sokal pumps the acid through the porous walls of concentric cups, which are filled with the lead active materials.

In the other type of cell, which generally would involve the circulation of electrolyte also, a liquid or gas capable of being oxidized reacts through a porous diaphragm with another similar substance capable of being reduced. The energy ordinarily given us as heat in such chemical reactions is thus obtained as electrical energy. Thermo-chemical formulæ will show what E.M.F. can be expected from a given reaction, thus foretelling its practicability. Basset describes as example of this cell, wherein the energy is obtained from the reaction of bromine or nitrous acid upon sulphurous acid in sulphuric acid, both electrodes being carbon. The reaction using bromine, which gives about 0.6 volt, is one of oxidizing SO_2 to H_2SO_4 and reducing Br to HBr.

The structure used by Basset is shown diagrammatically in Fig. 2. Carbon plates *1*, *5*, *9*, *13* are held between insulating frames *2*, *4*, *6*, *8*, *10*, and *12* of celluloid and separated by porous diaphragms *3*, 7, and *11*. The path of one liquid is indicated by the arrows, the entrance being at *H* and the exit at *K*. The other liquid circulates similarly in the other compartments.

There is a wide open field for those working on these last mentioned theories, especially in the use of organic compounds, many of which have high calorific values, such for example as the explosives. As a result of this future progress, we will soon run our cars by electrical power furnished from two tanks or packages containing, as it were, concentrated energy which can be set free in a battery. Even to-day we have a forerunner of this in the use of steel tanks of liquid chlorine or compressed hydrogen and oxygen in the gas battery.

Machines for Printing Railroad Tickets

(*Concluded from page 248*)

gear which meshes with a bevel gear on a main vertical shaft. On this vertical shaft is secured a circular table. Near the edge of the table is a second vertical shaft intermittently driven which operates mechanism for feeding forward a strip of paper and printing thereon the main body of the ticket. The strip of paper then passes over an aperture in the table. A cutting device then descends and cuts off the part required for the ticket, and at the same time the date is stamped on the back. The table is now rotated to bring the ticket under the printing wheel mounted on the top of the machine. This wheel is composed of disks *A* and segments *B* carrying on their peripheries name plates of the various stations on the railway system. The main wheel, as well as each disk, is rotatable which makes it possible to arrange a very large number of type plates in a small compass. The name plate of the station desired is brought immediately over the table, and when by rotation the ticket arrives under the type plate, a plunger rises and presses the ticket against such plate. As the table moves on, a numbering device stamps a serial number on the ticket. For inking the name plate and the numbering plate, an inking ribbon in the form of an endless belt is used between the ticket and such plates. A strip of paper for auditing purposes, carried by unwinding and winding rolls, passes transversely between the folds of the inking ribbon, so that the place of destination and number is printed on such strip for each ticket printed.

In the machines just described, provision is made for numbering all the tickets with one serial number, but in the next machine (Fig. 3) the tickets to each station have their own serial number. In this machine, there is a horizontal axle carrying at the front of the machine a disk *D* having the names of various stations marked thereon, and inside the casing a similar disk carrying on its periphery type plates for printing the names of such stations and occupying the same relative positions as the names on the front disk. At one end of each type plate are mounted numbering disks which are operated each time such type plate is brought into use so as to number consecutively the tickets sold to such station. On the other side of the disk bearing the type plates are located small numeral disks which are operated each time a ticket is printed for the purpose of registering the total number of tickets sold. In order to make up a report of sales, the inventor has provided a web of paper mounted on suitable rolls, and at any time these rolls may be thrown into operation so that the web is impressed against each type plate and its serial number in turn. By this means the [illegible]

The last considerable improvement in these ticket printing machines was the addition of the cash register feature. Such a machine is shown in Fig 4. In this machine the date is first printed on the back of the paper strip, and this strip then passes between an impressing roll 1 and a printing cylinder 2. On the periphery of this cylinder are fixed type for printing the general reading matter such as the name of the railroad, station where sold, conditions of sale, etc., and also a groove for holding the type bar for printing the destination. These type bars are normally carried by spring pins on two endless bands 3 mounted on two drums 4. Mounted alongside the type bar carrier are two sprocket belts 5, one of which passes around a fixed sprocket wheel on the axle of one of the drums, and the other over an idler on such axle. To the first belt is secured a carriage which slides on a rod mounted parallel to such belts. At the front of the machine are arranged several banks of keys similar to a cash register, there being one key for each station, and such keys being arranged in the same sequence as the type bars on the carrier. When one of these keys is depressed, the carriage is made to clamp the second or power driven sprocket belt at the proper place so as to bring the proper type bar opposite the slot in the printing cylinder. At this point the carrier stops and a device grips the type bar and inserts it in the cylinder, which then rotates to print the ticket. When the cylinder has completed its rotation the type bar is removed to the carrier and the carrier is then made to assume its original position.

The end of each type bar is notched in accordance with the price of the ticket to the station, and ratchets or slides are made to move up against this notched end every time the type bar is used. These racks or slides set in motion the mechanism for use in recording the amount of sales. Underneath the registering mechanism, the auditing sheet is made to travel, and each time the printing cylinder revolves, the total of sales is printed on the sheet and a hole is also punched in the sheet opposite the station to which the ticket is sold.

This machine is operated by a weight motor 6, and when the weight is wound up and the desired key has been depressed motion is transmitted intermittently to the various parts of the machine for performing the following operations: the proper type bar is brought opposite the slot in the printing cylinder and transferred thereto, the printing cylinder revolves once, printing the ticket on the upwardly moving strip, the type bar is returned to the carrier and the carrier moves back until the type bars are in their proper positions. While this movement is taking place, the registering disks are advanced in accordance with the price of the ticket and the total amount is printed on the auditing strip. Likewise, the auditing strip is punched in the proper place and the printed ticket is cut off.

A new railroad ticket printing machine which is expected to facilitate the sale of tickets has been introduced on the Prussian Government Railroad. The machine prints tickets to all stations, and the ticket seller has nothing to do but to put a blank ticket form into a slot and to set the machine by means of pushing a carriage so that it will print a ticket as he wishes. The apparatus prints the ticket, also a control slip which shows all the tickets that have been printed and sold. The control over the business the ticket seller has been doing is thereby complete. The printing of the tickets takes less time than the hunting for the ready made tickets in the different pigeon holes, for the ticket seller has nothing to do but to take a piece of cardboard from a heap at his side, to insert it into the slot and to move two levers.

From the foregoing, it will be seen that much thought and study has been devoted to the development of this class of machines, and while the latest types are decidedly complex, they are not unduly so considering the results accomplished. The

inherent difficulties are no greater than those met with in the cash register now of such general use, and there appears to be no good reason why these ticket machines, when once perfected, should not come into general use.

A New Gear Engine

(Concluded from page 249.)

"The advantage of this cycle lies not so much in the cycle itself as in the form of the machine which the cycle permits to operate on it. The engine possesses the same advantages as the turbine over the reciprocating engine in that all of the parts in contact with the steam are at a constant temperature for any constant load condition, and the heat losses due to cylinder condensation in the reciprocating engine are obviated. The engine operates at much higher speeds than piston engines and, therefore, allows the use of smaller and consequently cheaper constructed machinery, such as electric generators, centrifugal pumps, etc. As it uses the pressure energy of the steam instead of the kinetic energy it does not have to meet the difficulties encountered by the steam turbine in dealing with enormous steam velocities which have given no very great trouble with large size turbines, but have rendered small turbines uneconomical."

The novelty of this new system of compounding, when considered in conjunction with the good water rate already obtained by the single-stage unit, furnishes very interesting computations relating to its future possibilities. Mr. Charles H. Clark, the inventor of this gear engine, is not the first to devise a gear engine. Many attempts have been made to produce a practical engine of this type in the past. The most important differences between the Clark engine and other gear engines resides in the fact that the gears A are inclosed at their meshing point by a stationary structure (with sufficient clearance to allow the gear to revolve freely) to direct the fluid against the teeth, but elsewhere they are not inclosed at all except of course by the casing B, which leaves plenty of space for unimpeded movement or expansion of the fluid. Heretofore the inclosure employed has always been either so close to the gear not only at their meshing points, but elsewhere also, that a powerful suction is produced which opposes the rotation of the gear, and hence cuts down the efficiency of the engine, or else the structure including the gears at their meshing points has been so mounted that it can be moved by the driving fluid, the idea being that it will in this way be self adjusting. But this does not work in practice, for it permits wasteful leakage and binding of the parts which should move freely with the least possible friction.

Quite as interesting as Mr. Clark's engine are the accessory mechanisms introduced by the inventor to adapt his engine to practical working conditions. The drawing, Fig. 2, shows a novel speed gear by which the speed of the engines may be reduced 20 to 1. The power shaft G is formed with teeth cut therein, adapted to be engaged by the teeth of six spur wheels H. The spur wheels are arranged in two sets of three, with their shafts arranged in a circle about the shaft G, and disposed sixty degrees apart. These shafts in turn bear pinions which engage a single spur gear mounted on the driven shaft. As the power shaft G is surrounded on all sides by spur gears, practically all of its teeth are in engagement at all times, and there is no thrust to contend with. As each tooth of the power shaft is doing its share of work, the teeth may be made much smaller than would otherwise be required. In the illustration, which is drawn to scale, the power shaft is but one inch in diameter. Yet through this small power shaft 40 horse-power has been delivered at a speed of 3,600 revolutions per minute and stepped down to 180 revolutions per minute at the driven shaft.

The power shaft is connected to the engine shaft with a flexible coupling. The

coupling consists of short spring rods arranged in a circle, something like a lantern gear This flexible coupling permits the power shaft G to find its own axis of rotation. In fact, the power shaft has practically no bearing other than that afforded by its engagement with the spur wheels H The tooth speeds afforded by this system of gearing are one sixth of that now employed in speed reduction gears, and about twice as much work is done the factor of safety being about twice as great at low speed. The gears do not travel over twenty feet per minute

Another interesting development in connection with this engine is a governor invented by Mr Clark The governor can be adjusted so that the speed will either increase or decrease as the load is increased and there is a point of intermediate adjustment which gives constant speed under all conditions The details of this governor are shown in Fig. 3. The balls of the governor are in the form of two sectors J, which engage a rack K, connected by suitable means to the throttle The speed of the governor varies as the radius of the circular path of the ball or weight about the axis of gyration of the governor and as the sine of the angular displacement of the center of gravity of the ball from the plane passing through the pivot of the ball perpendicularly to the axle As both of these quantities are variable Mr Clark has so designed his governor that the variation will be equal through a considerable arc of travel of the weight This he has succeeded in doing by placing the center of gravity of the weight J in such a position that at any given speed the torque or tendency of the weight to swing out varies directly as the displacement of the centers of gravity of the weight from the theoretical neutral position In the Clark governor the fulcrum of the governor ball is 2.5 times farther from the axis of gyration than the distance of the center of gravity from the fulcrum

Bee Insurance in Switzerland

THE latest of the diversified forms of insurance applicable to rural life and industries is the insurance of bees against foul brood, now in successful operation in Switzerland This dread disease, which is due to bacteria of extraordinary vitality is extremely infectious A hive in which it occurs is a source of danger to the whole neighborhood, since it is sure to be plundered by bees from other colonies which carry the diseased honey and comb to their own hives It is, therefore, a matter of great importance to the community that such hives should be promptly dealt with in the usual way the combs removed and burned new combs started and melted down after a few days, and the apiary completely disinfected

In order to minimize the loss in such cases, the Swiss Beekeepers Association decided a few years ago to establish a system of foul brood insurance to be compulsory upon all the members, about 7,000 in number The beekeepers pay a premium of 5 centimes (1 cent) a hive In return for this they are guaranteed free treatment of infected or suspected hives, instruction and assistance in disinfecting, and compensation to the extent of 75 per cent of the value of hives and comb destroyed by the inspectors. As a further means of protecting members, persons who are not policyholders are also aided and were, until recently indemnified for 50 per cent of their losses.

In December, 1909 the Swiss government decided to take over the duty of inspecting and treating diseased hives and the association was thus relieved of much expense Moreover, as all beekeepers are now obliged by law to sacrifice their hives when infected the association has no longer a motive for indemnifying non members and has ceased to do so.

In 1911 the number of hives insured was 105,170 cases of foul brood, 114, and the expenses of the organization, including claims paid, exceeded the premiums by 342 francs—a trifling loss for a mutual insurance society

History-Making Cars

By R. E. Olds, Designer

For 26 years, and in legions of cars, I have written a good bit of motor car history

Reo the Fifth sums up all the results of it. It embodies all I've learned.

This is the latest of my history-making cars And you who would know what time has taught will find it all in this 1913 chassis

Go Deep

Don't follow the trappings of a car

We don't minimize appearance equipment up to dateness One glance will show how highly we regard them

Here's a 17 coated body Here is deep rich upholstering made of genuine leather Here are electric lights comfortable springs nickel trimmings set in dash lights—comfort luxury and room

But those are easy and apparent features Makers dare not skimp them So you must go below these things to measure up a car

Basic Worth

And a new car's performance is no criterion of value Any modern car makes attractive demonstrations

The real question is how that car will perform in five years from to day What will be the cost of up keep and repairs? How will the car meet an overstrain? What troubles will it give me?

The answer to those things lies in the chassis There is where you should look

What You'll Find

In Reo the Fifth you'll find steel made to formula Steel which we analyze twice before using to be utterly sure of its strength

You'll find gears which were tested in a crushing machine of 50 tons capacity

You'll find 2 inch seven leaf springs made from just the center one third of the finest steel ingots Springs which we test for 100 000 vibrations

A $75 00 magneto—

A doubly heated carburetor—

A costly centrifugal pump

You'll find in all driving parts big margins of safety —not less than 50 per cent For all of these parts are tested to sustain a 45 h p engine

Costly Items

Those oversize tires—34 x 4 —cost $60 00 more than tires which some regard sufficient They are put on to double your tire mileage

There are in this car 15 roller bearings 11 of which are Timken They cost five times as much as common ball bearings Yet we might call this a Timken bearing car if we used but two such bearings

We use in this car 190 drop forgings to avoid all risks of flaws Steel castings cost one half as much

Each car must pass a thousand tests and inspections Nothing is left to chance Important parts are all fitted by hand—ground over and over to get utter exactness

Each engine gets five long continued tests three of which are unusual These tests require 48 hours After certain tests we take each engine to pieces and inspect every running part

To insure every precaution with every car we limit our output to 50 cars daily so men are never rushed

As a result every Reo the Fifth goes out a perfect car There are no defects no shortcomings to bother the man who gets it

The Hard Things

These are the things which are difficult and costly They add, I figure, $200 00 to the necessary cost of each car

It took years and years for me to learn their importance And it takes the user years sometimes to find out all they mean

It is easy to add attractions which all buyers see But these hidden things take courage

But all the faith which men have in me rests on this hidden worth Men have come to expect it and they'll always get it in any car I build

And the demand for this car—always twice our production—shows how men are turning to the well built car

One Rod Controls It

One small rod between the two front seats does all the gear shifting in Reo the Fifth The driver moves the rod only three inches in each of four directions

He sits on the left side as in all up to date cars so this rod comes at his right

There are no levers side or center Both brakes are operated by foot pedals So the driver's entrance on either side is entirely unobstructed

This form of control is exclusive with us is one of this car's great attractions It makes gear shifting as easy as advancing the spark

A thousand dealers handle Reo the Fifth. Write for our catalog and address of nearest showroom.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are sharp, the articles short, and the facts authentic, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement.

The Control of the Mississippi River

THE volume of correspondence which has reached this office since the publication on February 15th of our editorial on the problem of the Mississippi River proves that the magnitude and pressing importance of this question is appreciated not only by residents of the Mississippi Valley, but increasingly by the nation at large. We believe that before very long it will be understood that the regulation of a natural waterway that flows through the heart of the country is surely of equal importance to the construction entirely outside of our borders, of an artificial waterway such as we have built at Panama.

We draw attention to a letter upon the general subject of Mississippi River control, printed elsewhere in this issue, which draws attention to the fact that those who are interesting themselves in the problem are to be grouped broadly into two parties—the one believing that it is possible to regulate the Mississippi by properly revetted levees, the other holding that the best results will be obtained by a combination of dams for the storage of floods at the head of the Mississippi and its tributaries with a system of levees in its lower reaches.

In the editorial referred to we stated that those who believe that it is possible to control the Mississippi by building vast reservoirs near its headwaters have failed to appreciate the magnitude and cost of such reservoirs and the enormous areas of land that would have to be condemned for the purpose. It was shown that Government measurements, taken at the height of the recent flood, proved that at one particular point the river was flowing at the rate of 2,000,000 cubic feet per second—a maximum flow which is equal to twelve times the amount of water that passes over Niagara Falls.

These figures of total quantities are sufficiently large to prove that the regulation of the river by reservoir construction alone would be impracticable, even if the existing levee system were maintained at the present grade line. As between regulation by carrying the levees to a height that would absolutely control future floods, or building the levees to a lower height and constructing reservoirs to hold back a portion of the flood waters, there is of course a difference in cost and time of construction which could only be determined as the result of accurate surveys and estimates. We do know that the army engineers, with their long experience and a vast amount of accurate data at command, have made an estimate for complete control of the river by levees, of about $70,000,000 for the levee work and about $90,000,000 for the revetment to protect the levees, or a total cost for the whole work of $160,000,000. Whether it would be possible to make any serious reduction in this total by holding back a certain portion of the flood waters is a question upon which it is foolish to engage in any mere guesswork. There is at least a strong suggestion that any reduction in cost so secured would be inconsiderable in the statement of Col. Townsend before the House Committee, that if it had been possible to destroy the whole State of Minnesota (that is, hold back all the water that flows over it) there would not have been a difference of three tenths of a foot in the height of the last flood at Cairo. Furthermore, a reduction of three or four feet in the height of the flood by conversion of the St. Francis Basin into a storage reservoir, would have called for the sacrifice of some seven thousand square miles of country. Nevertheless, we believe it would be good policy to have estimates prepared as to the relative economies in time of completion, benefits conferred, and total cost, of a pure levee system as against a levee-and-reservoir system.

Referring to the statement of our correspondent that in the year 1717 a two-foot levee was ample to protect New Orleans from flood, whereas in 1912 twenty two feet were registered at the same city, we wish to point out that the difference may be regarded as being in a certain sense an eloquent tribute to the industry of the American people, in bringing into subjection the virgin lands of the Mississippi basin. Two centuries ago the melting snows and heavy rains were retarded in their flow from the higher to the lower levels by vast forests and thickly interlaced underbrush which has since been cut down and cleared away, and the flow of surface and subsoil water into the streams has been facilitated by the open ditch and the subsoil drain. It is quite possible that if two graphic curves were developed, one representing the rate of population in the Mississippi watershed, and the other the increase in height and volume of the Mississippi floods, there would be found to exist a surprisingly close relation between the two.

What the Rich Man Might Do for the Scholar

BUILDING libraries is a favorite pursuit of philanthropists. This proves that many benevolent persons prefer to minister to the mental rather than the material needs of humanity, a preference with which we are not disposed to quarrel. Just because, however, we heartily approve of libraries, we deplore the fact that the amount of money spent in creating them is out of all proportion to the amount spent in making them useful. A library is still a library, even though its contents are securely locked up from human sight, as in the case of the precious manuscripts said to be stored in the crypt of St. Sophia, at Constantinople. The admirable science of librarianism which has been mainly evolved within the past half century, has for its main purpose the removal of the invisible bolts and bars that obstruct access to libraries. Modern aids to reading and research, in the form of card-catalogues, indexes, bibliographies, and the like, have immensely facilitated the use of the great collection of books of which our civilization is so proud, but there is still an almost unlimited amount of work to be done in this direction.

Here is a suggestion for the rich man who wishes to vary the programme of library building. A library is primarily beneficial only to a restricted community. The benefits of good work in the bibliography are universal. Why not endow a bibliographic institute?

Gustav de Laval

IN his book "Great Men," Prof. Wilhelm Ostwald makes a scientific study of the life-history of the great scientist as a specific type of man. There is no doubt that such men do represent a specific type, or perhaps rather a number of specific types. Gustav de Laval, whose death was recently announced, was a striking example of the typical inventor, a mind ever busy on the solution of problems, a man who solves problems because he cannot help himself. Thus it came that not all of his inventions proved commercial successes, and those that did, enriched others perhaps more than their originator. It has been estimated that the cream separator and milk tester devised by de Laval have saved billions of dollars to the world's dairy interests. As for the steam turbine, one form of which is known by his name, though the entire field was opened by him, its value to the world needs no emphasis here.

Gustav de Laval was born on May 9th, 1845, in Sweden, though, as his name implies, he comes of French stock, one of his ancestors having settled in Sweden after serving in the host of Gustavus Adolphus. De Laval early showed an inclination for mechanics, and his parents wisely directed his education toward an engineering career. He entered the technological department of the University of Upsala in 1863, and three years later graduated with distinction. Then came a short period of practical experience in an iron mine and with a waterworks builder, followed by a post graduate course at Upsala, leading to the doctorate in 1872. Upon re-entering practical pursuits, he was sent to Germany to make a study of the manufacture of sulphuric acid, and upon his return to Sweden, he built the first sulphur burners in his country. Later he became constructing engineer at an iron works, where he introduced various improvements in galvanizing, the production of steel, and the extraction of phosphorus from iron ore.

The idea of the de Laval steam turbine came to him in the course of an experiment in sand blasting. The breaking loose of a steam jet was the fortunate accident which started the train of thought. An accident, also, it was that led him to his other great invention—the artificial cream separator. There was a large dairy on the iron works estate where de Laval was employed, and so, not unnaturally, the talk one day turned upon a new milk skimmer reported from Germany. It consisted essentially of a rotating barrel, in which the milk was placed. Centrifugal action hastened the separation of the cream, which was finally skimmed by hand as usual. This crude device formed the nucleus of de Laval's automatic centrifugal separator, in which the cream is discharged in a continuous stream from the rotating vessel. Such was de Laval's sense of honor that he refused to sell his invention until he had first given an option to the inventor of its crude prototype. As the latter, however, did not avail himself of this offer, de Laval proceeded independently with his own device.

De Laval was a great inventor, but he was more—he was a man of great character. His patriotism took the practical shape of services rendered to the State as member of the Lower and of the Upper House of the Swedish Parliament. From these activities he retired in 1906, finding that, after all, his best qualifications lay in other directions.

Sweden is justly proud of a noble list of great men, its sons. And in this list not the least is the late engineer and inventor, Carl Gustav Patrik de Laval.

Germany's Aeronautical Weather Bureau

THE first storm warning service for aeronauts on a national scale was that established by the German government at the beginning of the year 1911, as fully described in the article "An Airman's Weather Bureau" in the SCIENTIFIC AMERICAN of July 29th, 1911, p. 98. This unique institution has now been in operation over two years, and has amply justified its existence. Its history up to date is given in the last annual report of the Lindenberg Observatory, at which the service has its headquarters.

Beginning with last year, in addition to the center at Lindenberg, a second central station has been maintained at Frankfurt-on-the-Main. The principal pilot-balloon stations are Aachen, Frankfurt, Hamburg, Magdeburg, Berlin, Breslau, Königsberg and Bremen. These are provided with large balloons, capable of reaching an altitude of from 2½ to 5 miles (according to the size of the balloon) in about 40 minutes. Secondary stations, equipped with smaller balloons, are located at Bromberg, Dresden, Ilmenau, and Weilburg. Reports are also received from the independent aerological stations at Strassburg, Friedrichshafen, and Munich.

The telegraphic reports of upper-air observations received at the two central stations are combined with the ordinary low level weather reports collected at the Deutsche Seewarte, in Hamburg, and enable the authorities to issue twice-daily forecasts which state in very definite terms the conditions likely to be encountered by aeronauts at various levels for a few hours in advance. The forecasts and warnings are telegraphed to all the co-operating stations, and warnings are also telegraphed or telephoned directly to individual aeronauts and institutions that request them and are willing to pay a small fee for this service, in addition to the telegraph tolls.

Probably the most important development of the aeronautical weather bureau since it was established is the system of reporting thunderstorms. At first the attempt was made to utilize the services of a number of the ordinary volunteer observers who report by post to the meteorological institutes. This plan was not successful, as a great many observers did not live near enough to the telegraph offices to send their reports promptly—and delays are fatal in an undertaking of this character. Accordingly, with the approval of the postal authorities, a new corps of thunderstorm observers was organized among the 2d and 3d class postmasters (who are also telegraphers). In 1912 the number of these observers, all of whom give their services voluntarily, was 608. In addition, 18 important offices in large towns, which are the centers of the main telegraph lines running in all directions, report disturbances on the lines indicating the occurrence of electrical storms. The fact that reports from postoffices are treated as "service messages" insures prompt transmission, which is further promoted by the fact that the Lindenberg Observatory has a private wire from Berlin. By these means German meteorologists appear to have solved the important problem of giving aeronauts timely warning of all thunderstorms that enter or originate in the Empire. Most of these storms move in a general direction from west to east, and frequently assume the form of line-squalls, i. e., long zones of disturbance moving sideways across the country.

All the important aeronautical events of the last two years in Germany, including the army maneuvers, have made the fullest use of the new weather service, and it is now looked upon as an indispensable institution.

Engineering

That High-speed Submersible.—The high-speed submersible, of large displacement, designed to fight head-on and "rush" the battle line of the enemy, discharging its torpedoes at point-blank range, has again made its appearance (in print) and this time it is credited to the German navy A 25-knot, 3,000-ton submersible, with curved armored deck, rushing at a battleship across the 10,000-yard range, would be difficult to stop before she came within close torpedo range.

One Thousand Horse-power Diesel Engine.—As an instance of the large powers in which the Diesel engine is being built, we note that two 1,000 horse-power, two-cycle, four-cylinder, Carels-Diesel engines are to be installed in an Arizona mining property and that these engines are to deliver 1,000 horse-power at an elevation of 6,500 feet, the consumption not to exceed 0.48 pound of oil per brake horse-power per hour

Test of an American Diesel Oil Engine—After the publication of so many tests of the performance of European-built Diesel engines, it is interesting to study the records of a 225 horse-power Diesel engine, built by the Busch-Sulzer Engine Company of St. Louis, and tested by Prof A T Scott. The engine had been in service six months, and no preliminary tuning up was attempted The records show a fuel consumption of 10 8 gallons of oil at quarter load, 6.8 at half load and 6.2 at full load, or 0 441 pound of oil per net brake horse-power per hour The thermo-dynamic records based on net useful output showed 17 4 per cent at quarter load, 27.8 per cent at half load and 30.3 per cent at full load The results certainly speak well for American Diesel oil-engine practice

The Needs of the Navy—In a letter to the New York *Times*, the outgoing Secretary of the Navy, George v L Meyer, made a succinct statement of the needs of the United States Navy He stated that the battleship fleet should be maintained with 21 ships in the active fleet and 20 in the reserve fleet. The former should not exceed ten years of age, and those between ten and twenty years old should be placed in reserve We should have four torpedo-boat destroyers for every battleship, in addition to scout cruisers, submarines, supply ships, colliers, and minor auxiliary vessels. The building programme each year should be sufficient to replace those battleships which have reached in each year the limit of twenty years of age.

Piece of Rope Wrecks the "Lusitania."—The "Lusitania" has the telemotor system of steering gear, in which the movements of the steering wheel in the pilot house are transmitted hydraulically to the steering engine, several hundred feet away The falling of a small piece of rope or twine into the rack of the telemotor caused the same to bind and jam the steering gear This took place just as the "Lusitania" was entering Fishguard harbor, and was about to turn to port to avoid a steamer When it was found that the telemotor had jammed, an order was given to reverse the turbines at full speed The strain proved too great for the blades of the turbines, which became twisted out of their proper pitch It was found that over one million blades would have to be replaced, and the cost of the repairs will run up to several hundred thousand dollars.

Dock Commissioner Tomkins on 1,000-foot Piers.—In the opinion of Dock Commissioner Tomkins, no new 1,000-foot piers should be built above 46th Street (as was recently suggested by the Board of Estimate and Apportionment) but all such piers should be built south of the Chelsea district. He states that the cost of rock excavation at the site above 46th Street would, alone, exceed $4,000,000 per pier, and the time for building would be not less than four years. There may be some truth in what the Commissioner says, but we do not believe that either the cost or the time of construction would be so great as he states. According to his statement, a 1,000-foot pier could be built at the lower end of Manhattan Island in two years' time for a cost of less than $1,000,000. We are of the opinion that the piers in the lower section of the river should be built first, but that the site above 46th Street should be secured to provide for future contingencies.

Risk of Torpedo Maneuvers.—The loss of a German torpedo-boat destroyer with sixty-six officers and men—practically the whole complement—illustrates once more the grave risks of night maneuvers, when carried out by these craft in connection with battleships. In the particular maneuver in which the disaster occurred, the group of destroyers, in line abreast, passes through a column of battleships. It requires the nicest judgment of speed and distance to enable the captain of a destroyer to carry his boat through the interval between two battleships, which may be steaming at 15 knots or more, without being rammed. A slight misjudgment may bring the craft square across the bows of the big ship; and this is what seems to have occurred in the case of the recent disaster. The Germans are fond of this maneuver and similar accidents occurred in July, 1912, and in September of last year. These, however, are the risks which must be run if high efficiency in maneuvers is to be maintained.

Science

An Important Change in the Map of Asia has recently occurred. The vast region of Mongolia has ceased to be a part of China, and is now independent The Mongols are chiefly famous in the world's history as invaders and conquerors in Asia and eastern Europe They were vassals of the late Manchu dynasty, but not of the Chinese government, and their separation from China resulted automatically from the proclamation of a republic Their secession from China was aided by Russia, which thus secures a "buffer state" on its Chinese frontier

Vertical Component of the Wind—W Peppler has published the results of observations made at Lindenberg Observatory on vertical air movements, as deduced from variations in the vertical speed of pilot-balloons and sounding-balloons. The average rate of ascent of the balloon for each 500 meters was compared with the average for the whole ascent It was found that an increase in horizontal air movement was accompanied by an increase in vertical movement The author obtains from his observations the important general law that vertical displacements of the air occur from levels of smaller to levels of greater horizontal velocity

A Novel Educational Experiment has been in successful operation for some time at McComb City, Miss, according to a bulletin of the U S. Bureau of Education An arrangement has been made between the school authorities and the Illinois Central Railroad whereby boys may work every other day in the railroad shops and on the alternate days attend the high school They are known in the shops as "student-apprentices" and receive a minimum wage of 12 cents an hour By this plan the boys not only pay their way through school, but at the end of the four-year high school course are able to draw a man's pay at a trade, in case they do not find it feasible or desirable to proceed to the university

C. G S. Units in Meteorology—The vehement discussion that has been going on among meteorologists for about six years as to the desirability of making certain radical changes in meteorological units, especially those used in upper-air research, is likely to culminate at the forthcoming meeting of the International Meteorological Committee (April, 1913) The most important change proposed is the substitution of the "bar" and its submultiples for the units now in use for expressing atmospheric pressure The bar is a pressure of 1 megadyne per square centimeter, and corresponds to a reading on the barometer scale of 750 1 millimeters or 29 531 inches. Barometric readings would accordingly, be expressed in millibars, or thousandths of a bar A dynamic unit of this kind would undoubtedly be convenient for mathematical use in certain physical investigations, but whether its general adoption is feasible or even desirable is a grave question Unless adopted universally—a step that would necessitate the reconstruction of existing barometers all over the world, and the conversion of a colossal body of records tables, etc —its introduction would simply lead to the existence of three kinds of units in place of the two—metric and English—which are now in use (and which are one too many!)

The German Antarctic Expedition, under Lieut Filchner, recently returned to Buenos Aires without having accomplished its chief purpose, which was to land in Antarctica and push into the interior of that continent. After traversing a belt of drift ice 1 200 miles wide, new land was found in February 1912 at latitude 76 degrees 35 minutes south, and longitude 30 degrees west, i e, part of the shore of Weddell Sea, and evidently a southwesterly continuation of Coats Land In honor of the late ruler of Bavaria the patron of the expedition, this land was named "Prince Regent Luitpold Land" (Why not simply "Luitpold Land"? Antarctica is sadly burdened with needlessly long names.) The general course of this land was traced as far south as 79 degrees In latitude 78 degrees an ice-barrier was discovered, extending west from the coast, and was named "Kaiser Wilhelm Barrier" A landing was effected on the barrier and a station established, but soon afterward part of the ice on which the station stood was broken off by a high tide, and the explorers had to regain their ship as best they could The vessel then turned homeward, but on March 9th was caught in an ice-floe, and drifted helplessly until November 26th, when it was finally extricated by blasting During this long drift oceanographical and meteorological observations were carried on Weddell Sea was found to be shallow near the barrier, but very deep (about 17,000 feet) in the middle, and separated from the Atlantic Ocean by a ridge or rise, with a depth of about 3,300 feet. The currents seem to be controlled by the winds attending a quasi-permanent barometric depression overlying Weddell Sea. During the same drift an eight-day sledge expedition was made to the westward in an unsuccessful attempt to find the conjectural Morell Land. The expedition had the misfortune to lose its sailing-master, Capt. Vahsel, who succumbed to heart disease on the outward journey The equipment of the party is reported to be intact, and another attempt to effect a landing in Antarctica will be made next December.

Aeronautics

A New Cross-country Speed Record.—On March 4th the French aviator Guillaux who has recently made new speed records when carrying a passenger, flew in his 70 horse-power Clement-Bayard, all-steel monoplane from Savigny-sur-Blaye to Paris, a distance of 118 miles in one hour, thus breaking all records for speed across country On February 12th he made records of 391 9 kilometers (243 5 miles) in 4 hours, and 410 kilometers (254 8 miles) in 4 hours, 10 minutes and 40 seconds over a 10-kilometer course when carrying a passenger His average speed was more than 62 miles an hour

The St. Cyr Institute—Regarding the Aerotechnic Institute of St Cyr, near Paris which we recently illustrated, the annual report shows that even at the start there were fifty-two demands for tests of aeroplane surfaces and the like, or for information on allied subjects The large laboratories, testing halls and experimental tracks under Prof Maurain's direction are well adapted for this work Among others researches were made upon propellers at various speeds Capt Riviere also tested small models of propellers with the blowing machine Profs Toussaint and Lepere made tests upon recording instruments which are designed to be used on aeroplanes during the flights

A New Altitude Record of Nearly $3\frac{3}{4}$ Miles. At the Bue Aerodrome on March 11th M. Perreyon, on a Blériot monoplane succeeded in reaching the tremendous height of 6,000 meters (19,685 feet) He thus beat the records of Legagneux (5,450 meters or 17,880 feet on September 17th 1912) and of Garros at Tunis (5 610 meters or 18,400 feet on December 11th 1912) by a wide margin The atmosphere is only about half as dense at these great heights as it is at the earth's surface Not only does this affect the lifting power of the aeroplane but it reduces the horse-power of the motor as well, so that it is doubtful if a machine will ever be able to climb to a height much greater than four miles Then too, there is the difficulty in breathing and it will be imperative for the aviator to inspire oxygen

From France to Italy by Hydro-aeroplane—The first hydro-aeroplane trip from one country to another was made on March 4th, when MM Laurens and Schneider, on a Deperdussin monoplane, traveled from Beaulieu-sur-Mer to Genoa in 1 hour and 52 minutes running time or but 5 minutes more than the time made by Garros alone in the Paris-Rome race of 1911 Although the sea was calm, the aviators claim they experienced air holes A leaky gasoline tank caused them to stop at Spotorno, where they were long delayed The flight was started at 8 45 A M, and Spotorno was reached in an hour After resuming the flight at 5 20 P M 40 minutes sufficed in which to finish it despite the fact that from Sestri Ponente the machine was run on the water on account of fog The hydro was moored to a battleship and the aviators received an ovation

Monoplanes vs Biplanes for Military Use—Last year a number of accidents happened to monoplanes at the commencement of the British Army maneuvers with aeroplanes of different types, so that the War Office decided to forbid their use by the officers and at the same time appointed a commission to look into the matter of comparative safety of monoplanes and biplanes as it was claimed that the former were more dangerous The commission has now published its report and it appears that nothing justifies the idea that the accidents are due to any special class of aeroplanes but come only from lack of care in assembling the machines In general, the tests made by the experts seem to show that biplanes are not any more stable than monoplanes, and it is to be remarked that many pilots prefer to use the monoplane as it is simpler and is less fatiguing to handle Several points are recommended which should be looked after in both classes of flyers one of these being an increase in the stay wires so as to give greater strength Landing on the ground should be done gradually and not in a sudden descent, as this is a source of danger
